

Hatch earlier or late? Survival of sardine (*Sardina pilchardus*) juveniles in response to environmental variability, parental effects, and growth conditions.

Andreia V. Silva*, Isabel Meneses, Susana Garrido, Paulo B. Oliveira, Eduardo Soares, Cristina Nunes and Alexandra A. Silva

Background

- Sardine is a very important resource in Iberian Peninsula, namely in the Portuguese coast, where it is the main target species of the purse seine fishery .
- The Northwest Portuguese waters are the main nursery area of sardine in the Iberian Peninsula.
- Complex area: upwelling events, river run off.

Background

- Recruitment to the Iberian stock shows inter-annual fluctuations, a cycle with a periodicity of 4 years and a long term downward trend.
- These fluctuations likely result from factors that act on early life-history stages, which are thought to be strong affected by environmental and ecosystem changes and maternal conditions.

Recruitment (age 0)

Fig. Sardine time series recruitment. Source: ICES, 2021 (advice sheet)

Goals

01

Relate the seasonal abundance of survivors with female reproductive activity and body condition and with sea surface temperature, chlorophyll-a and upwelling at the time of hatch.

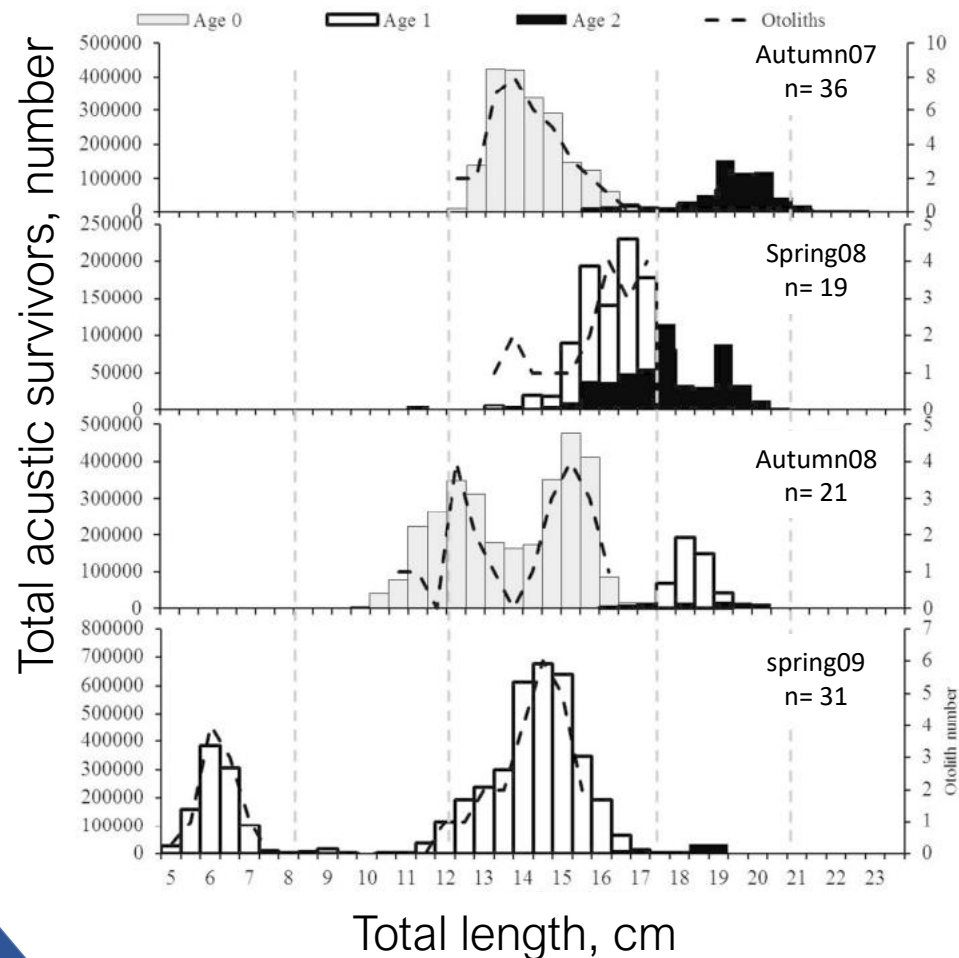

02

Relate survivorship with larval and early juvenile growth

Methods

DATA COLLECTION - Surveys

- Random number of sardine juveniles by length distribution from 4 surveys

- Sardines were measured (nearest 0,5 cm) and both otoliths were extracted.

Methods

Daily age analysis

- Micrographs were manually combined (200x).
- Nucleus area was read at 1000x.
- Measure of increments width.
- Daily ages were calculated from the total number of rings plus 4 days, the average duration of the first-feeding period.
- The hatch date was calculated subtracting the age from the date of sampling.

Methods

DATA COLLECTION- Monthly samples
at harbour

- Parental Variables

- Gonadosomatic index (GSI) = Gonad Weight/Gutted weight x 100; for big (TL=> 19cm) sardines and small sardines (TL< 19 cm).
- Fulton's condition index (K) = Gutted weight/length³ x 100; for big and small sardines.

- Environmental variables

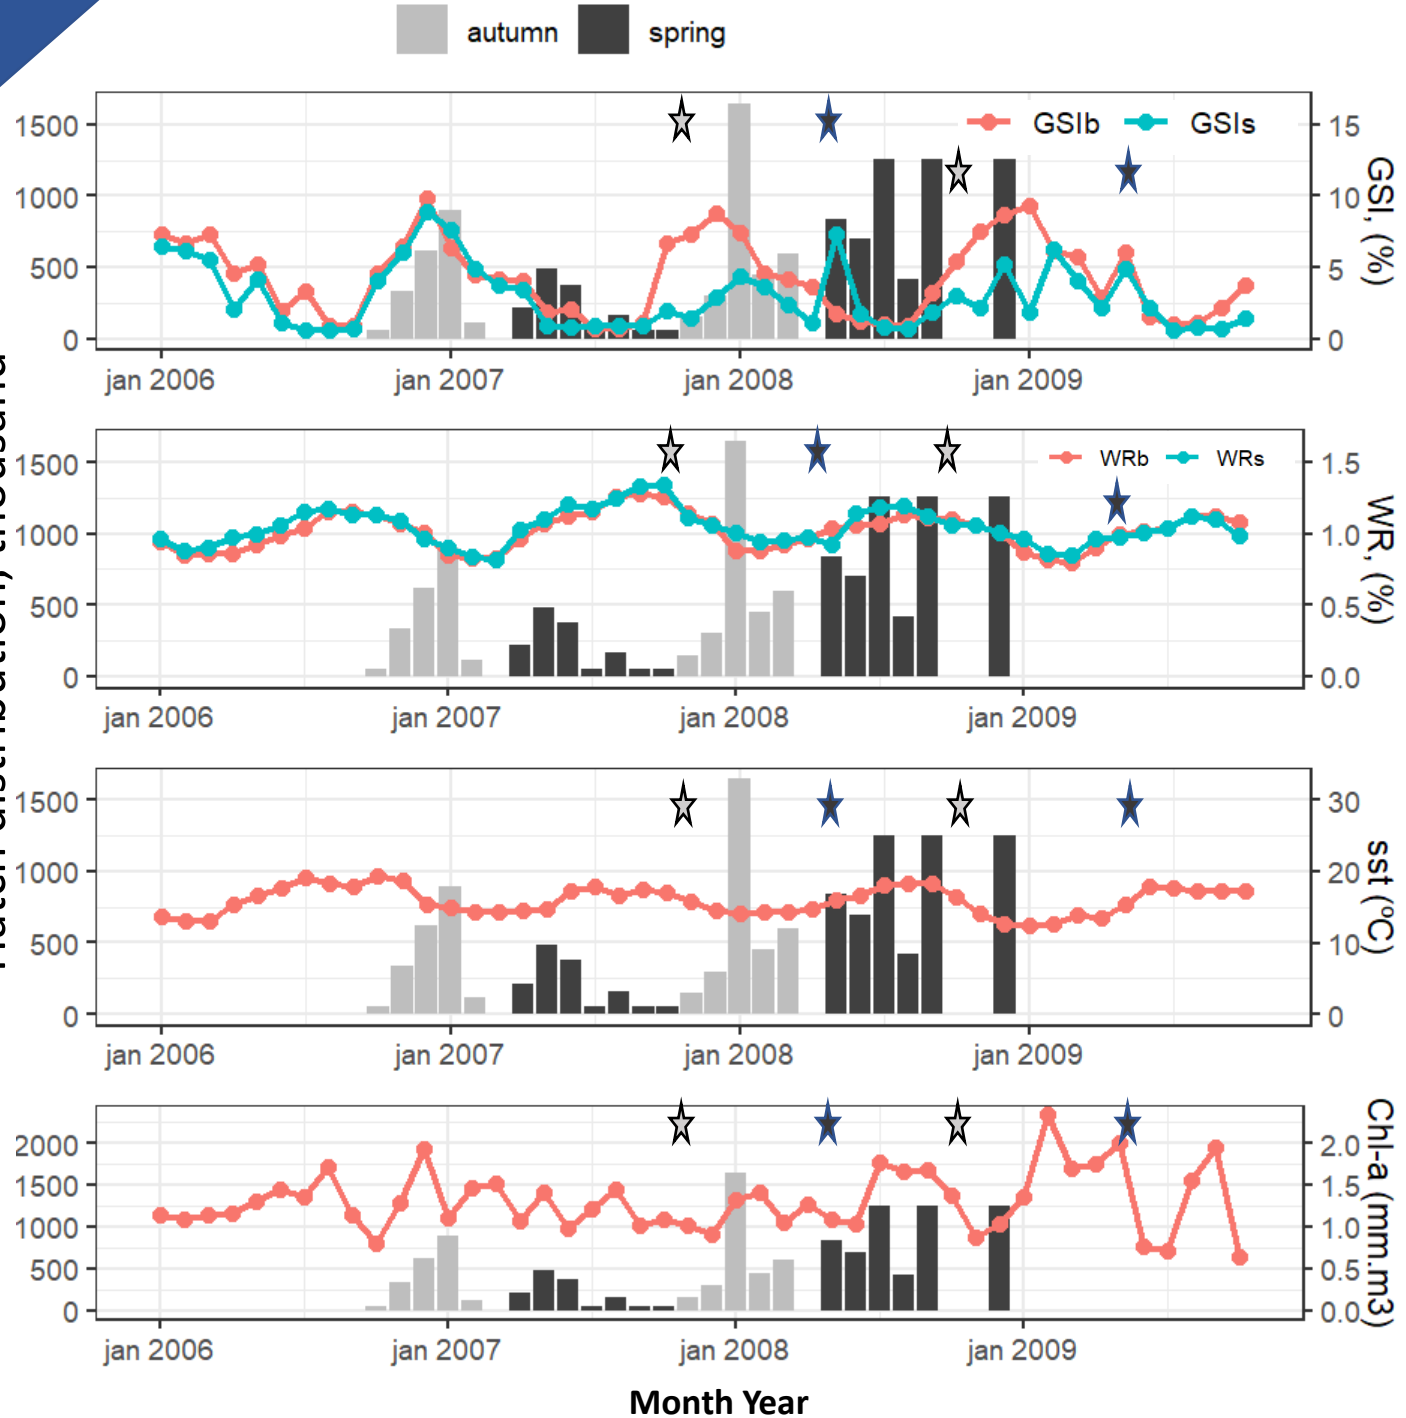

- Sea Surface Temperature (SST)
- Chl α
- Upwelling (Upw)

} North Atlantic Regional SST, provided by Ocean and Sea Ice Satellite Application Facility (EUMETSAT)

Results

Hatch Dates

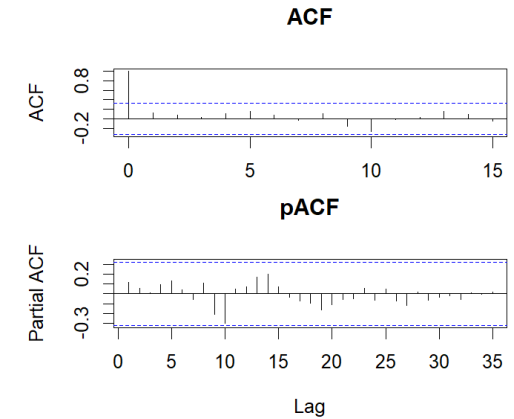

Hatch distribution, thousand

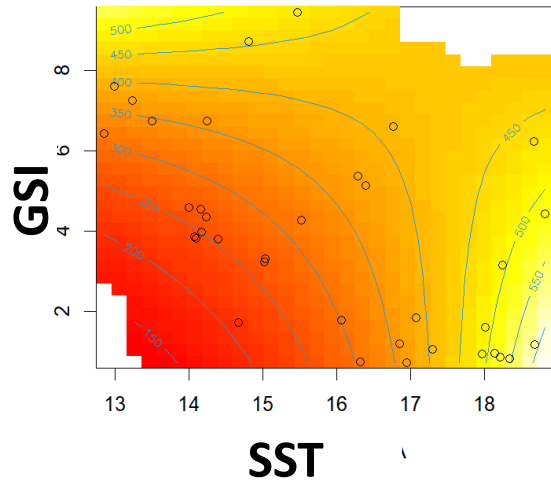

- Hatch of winter survivors coincides with a period of:
 - High values of GSI lagged 1 month
 - Low values of WR lagged 1-2 months
 - Low values of SST
- Hatch of summer survivors coincides with a period of:
 - Low values of GSI
 - High values of WR
 - High values of SST
- No consistent relationship between Chl α and hatch distribution

Results

Survivors and parental and environmental variables

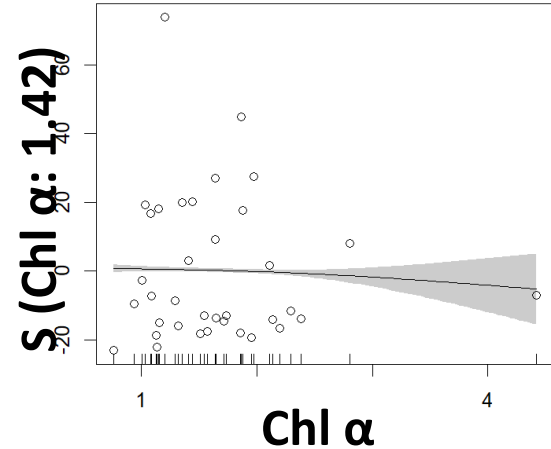

p_value = 0.75

$\text{gam}(\text{survivors} \sim \text{te}(\text{SST}, \text{GSI}, \text{k}=\text{c}(4,4)) + \text{s}(\text{Chl } \alpha, \text{k}=3) + \text{s}(\text{upwel}, \text{k}=3), \text{family}=\text{quasipoisson}, \text{gamma}=1.4)$

- High number of survivors are found with high values of GSI and low SST and at low levels of GSI and high SST

p_value = 0.27

Deviance explained = 18%

Results

Survivors and parental and environmental variables

(a)

(c)

(e)

(b)

(d)

- Number of survivors didn't show autocorrelation.
- Hatch dates and GSIb show significant negative correlation at lag 4.
- No significant correlation with GSI peak of small females.
- Survivors lags 3 months from the WR peak of large and small females.

Results

Survivors and parental and environmental variables

(f)

(g)

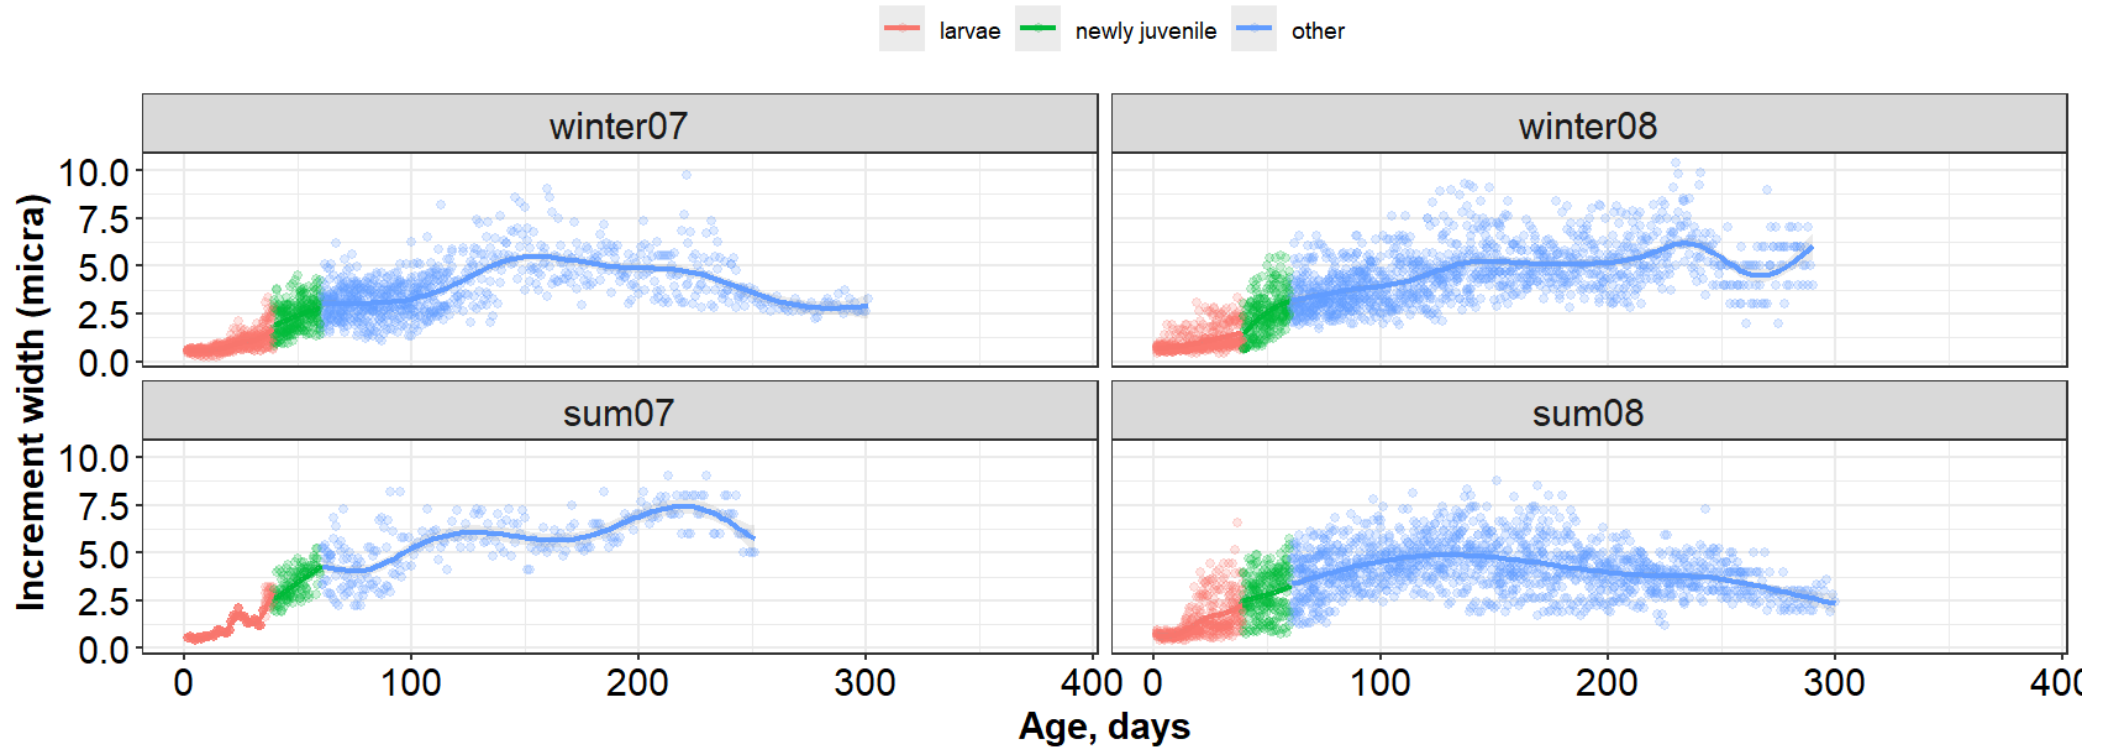

(h)

- No significant correlations were found between survivors and SST.
- The Chl α is significant correlated with survivors hatched 5 months before.
- The upwelling is significant correlated with survivors hatched 3 months after

Results

Early live growth

- Sardines hatch in winter showed sub daily rings difficult to distinguish.
- First daily ring was visible on average $5.2 \mu\text{m} \pm 0.4 \text{ SD}$ distance from the nucleus.
- Increment widths under 15 days vary between $0.24 \mu\text{m}$ and $0.44 \mu\text{m}$ ($0.65 \pm 0.2 \text{ SD}$).

Results

Early live growth

```
gamm(width ~ s(n,by=season)+s(upwel),  
random=list(otol=~1),  
correlation = corARMA(form=~ growth|otol,p=3))
```

s (daily age in winter): p_value <2e-16***

s (daily age in summer): p_value <2e-16***

Deviance explained = 60.2%

What's best? Hatch earlier or late?

Winter survivors

Months of births

October - March

Spawning season

Main spawning season

GSI

Medium or higher;

SST

Lower or intermediate

Growth early stages

Slow growth in larval stages

Spring Survivors

May - September

Outside main spawning season

Minimum

Higher

Fast growth in larval stages

Discussion

Winter Survivors

- More survivors when:
 - GSI higher
 - SST lower

- Our results indicate hatch peak outside the reproductive peak

Other environmental factors conferred the periods of intermediate GSI values with advantages that enhanced their survival

Discussion

Summer Survivors

- More survivors when:

- GSI lower
- SST higher
- W_r higher

- Hatch peak occurs with low GSI values, however:
 - Some residual spawning activity,
 - better maternal condition,
 - environmental conditions.

Faster growth in larval and juvenile stages could improve the changes of survival.

Discussion

Winter vs Summer: growth differences

Winter survivors

SST \approx 14°C

Energy accumulation in summer months, to produce higher quantity of eggs in winter.

Summer Survivors

SST \approx 18°C

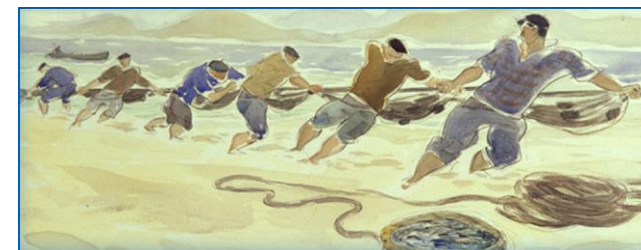

More food and highest temperatures seems to be related with faster larvae growth.

Sardine seems to be subject to growth-selective mortality

Future Research

- 2007 and 2008 were atypical years in terms of environmental conditions (PBOliveira, pers. comm);
- Compare with other years with contrasting recruitment
- See egg abundances for the same area and seasons;
- Examine variability of the circulation pattern;
- Include zooplankton abundance in the analysis.
