²Pacific States Marine Fisheries Commission

³NOAA Fisheries Northwest Fisheries Science Center, U.S. Department of Commerce

Research Objectives:

1. Has larval and juvenile Small Pelagic Fish (SPF) **abundance and timing shifted** in the northern California current (NCC) since 1998?
2. Can we determine if **ocean conditions** are associated with observed changes in SPF?
3. Does the **condition** of SPF differ between years and has **predator-prey dynamics** of a piscivorous predator shifted with observed SPF changes?

Small pelagic fishes of our study

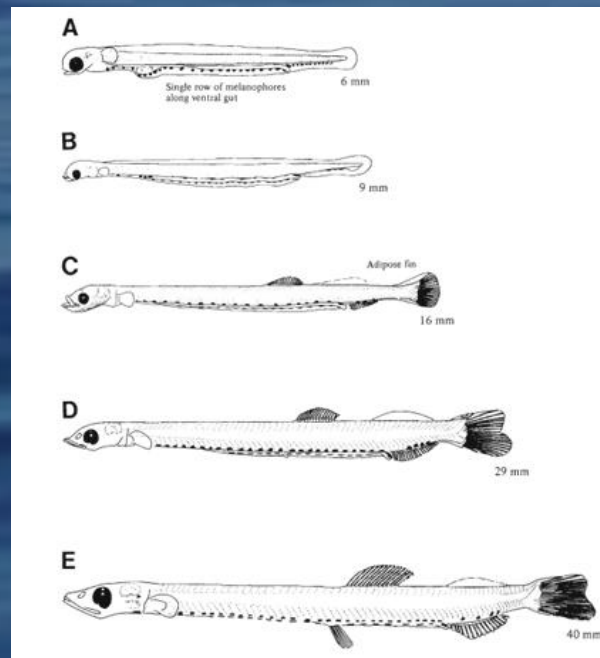

northern anchovy

Spawn in spring & summer in offshore waters of the NCC

Smelts (6 taxa)

Spawn in winter-spring in nearshore water of the NCC

Pacific sardine

Spawn in spring & summer in offshore waters of the NCC

Other small pelagic fishes in our coastal study area (not part of the talk)

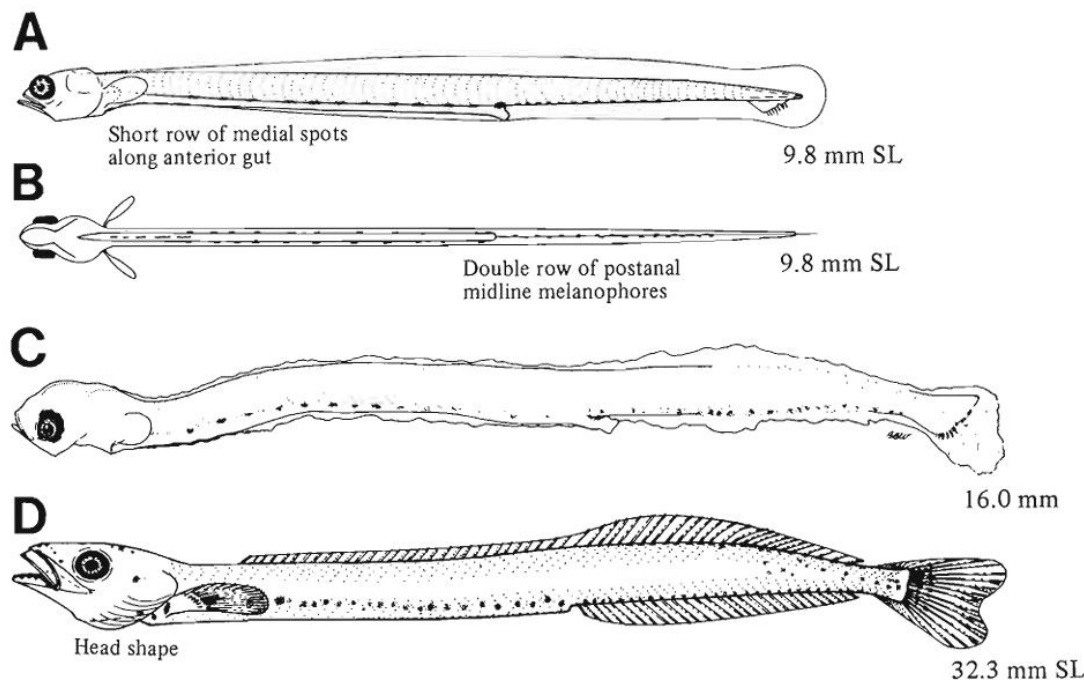

Pacific herring

Winter bay spawners
in the NCC

Pacific sand lance

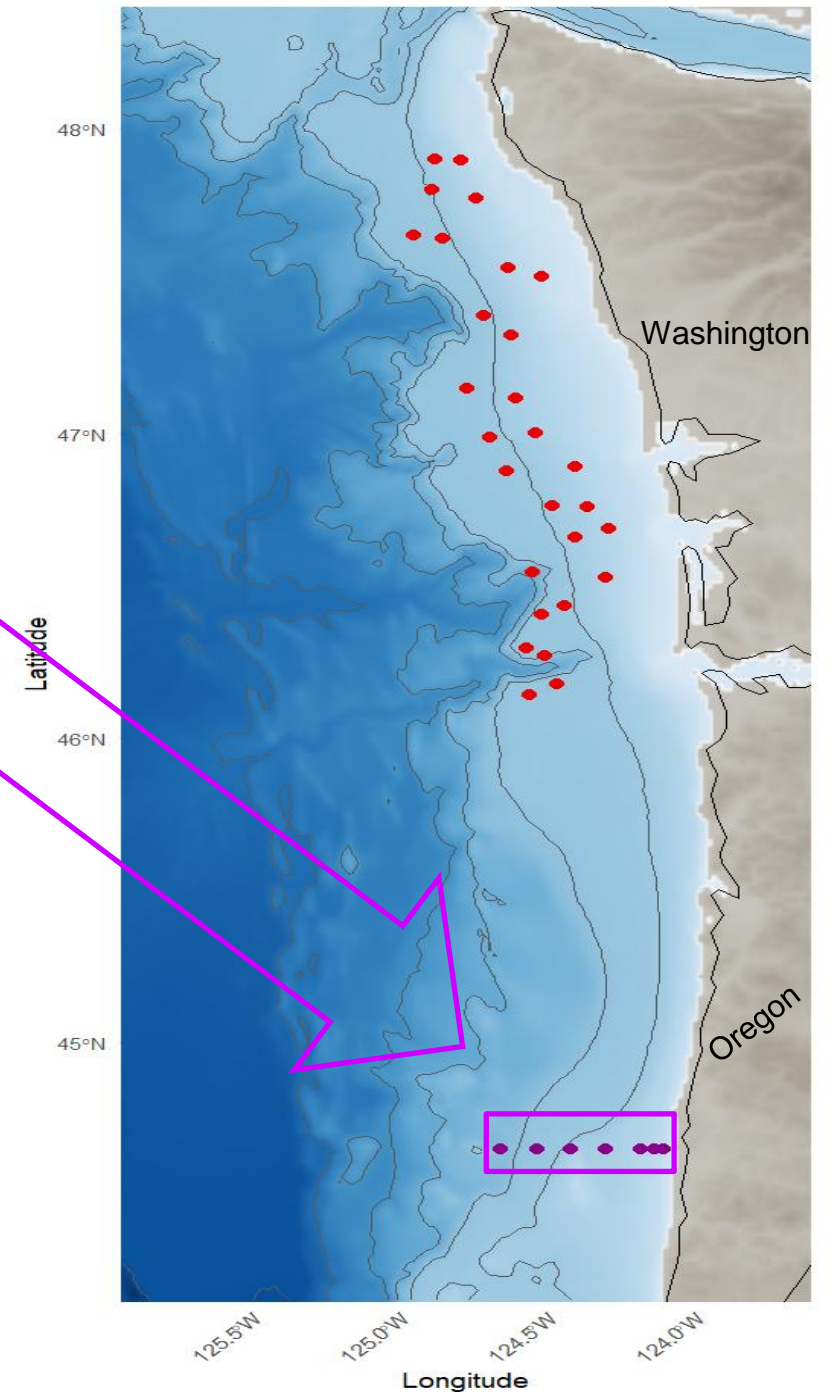

Winter nearshore spawners
in the NCC

Data on ichthyoplankton were from:

Newport Hydrographic (NH) line (44.65° N)

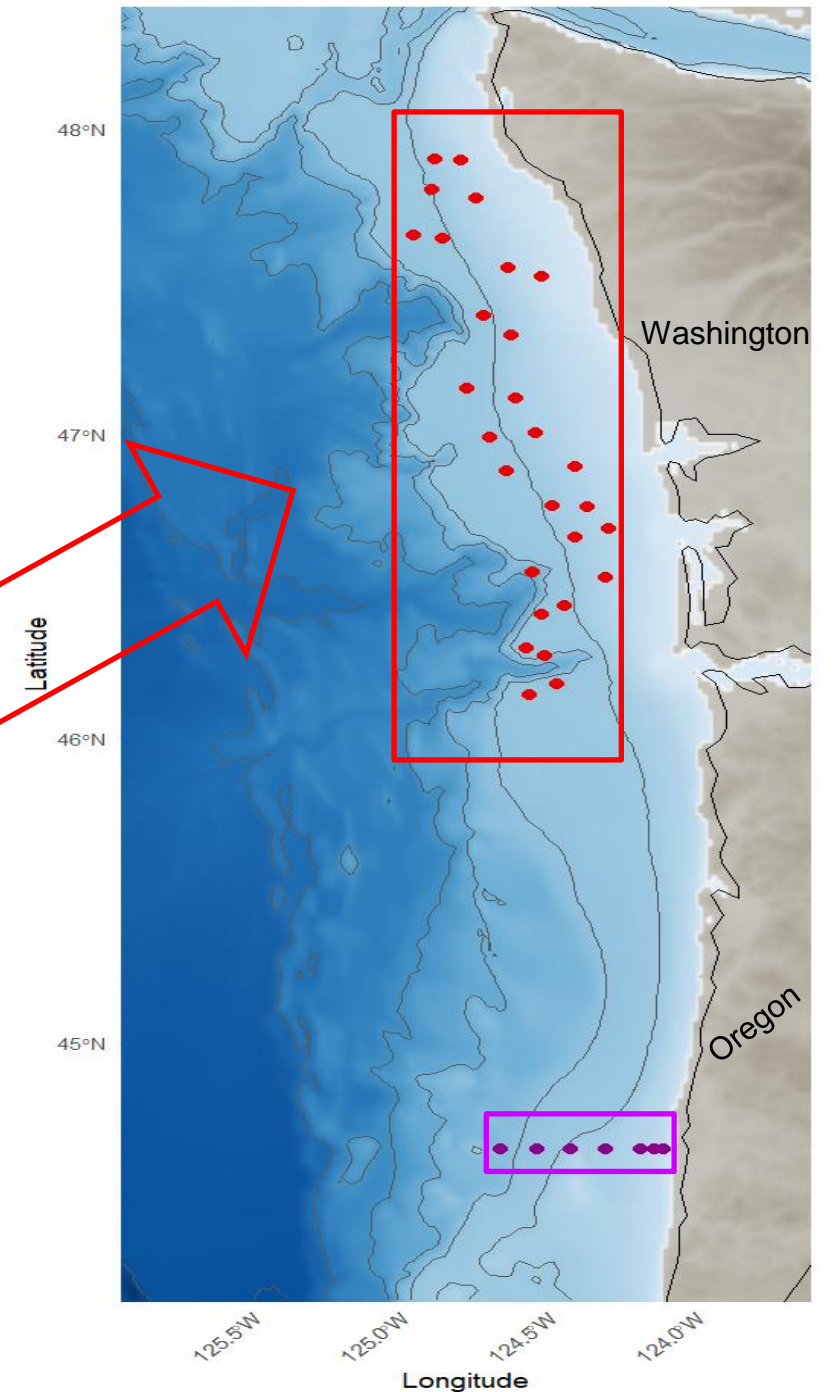

- 60-cm bongo net with 333- μm mesh towed obliquely to 30-m depth central Oregon coast 1998-2025 **bi-weekly**

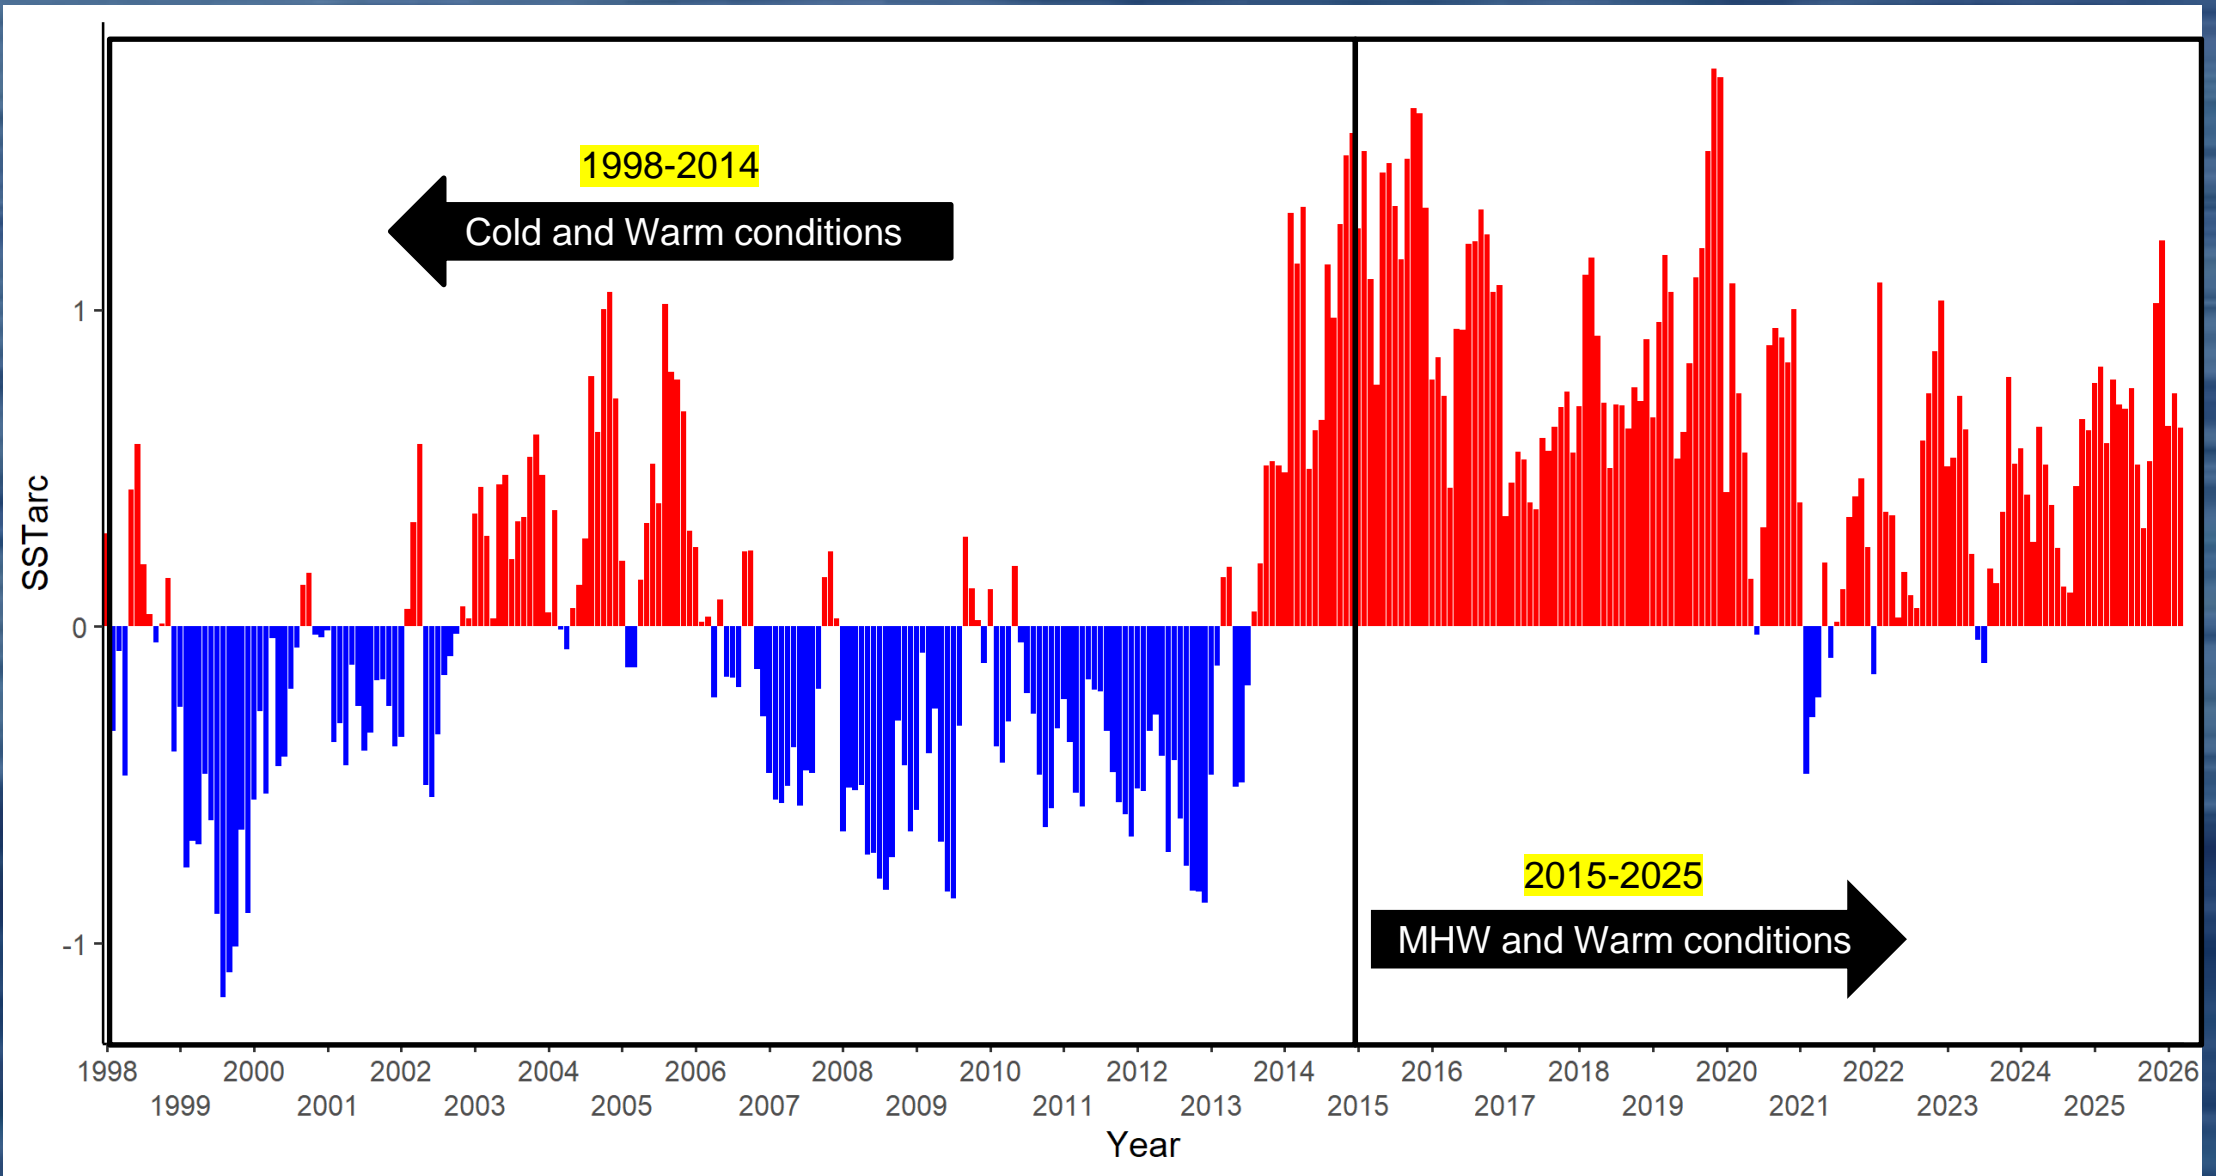

Data on juvenile SPF and juvenile salmon were from:

Juvenile Salmon Ocean Ecosystem Survey (JSOES)

- 30-m wide trawl net with fine-mesh liner towed at surface to 20-m depth along Washington coast (46- 48°N) 2017-18; 2021-25 in May. Salmon were also sampled 1999-2012; 2015-2016

Monthly sea surface temperatures have been anomalously warm in the NE Pacific ocean since 2015

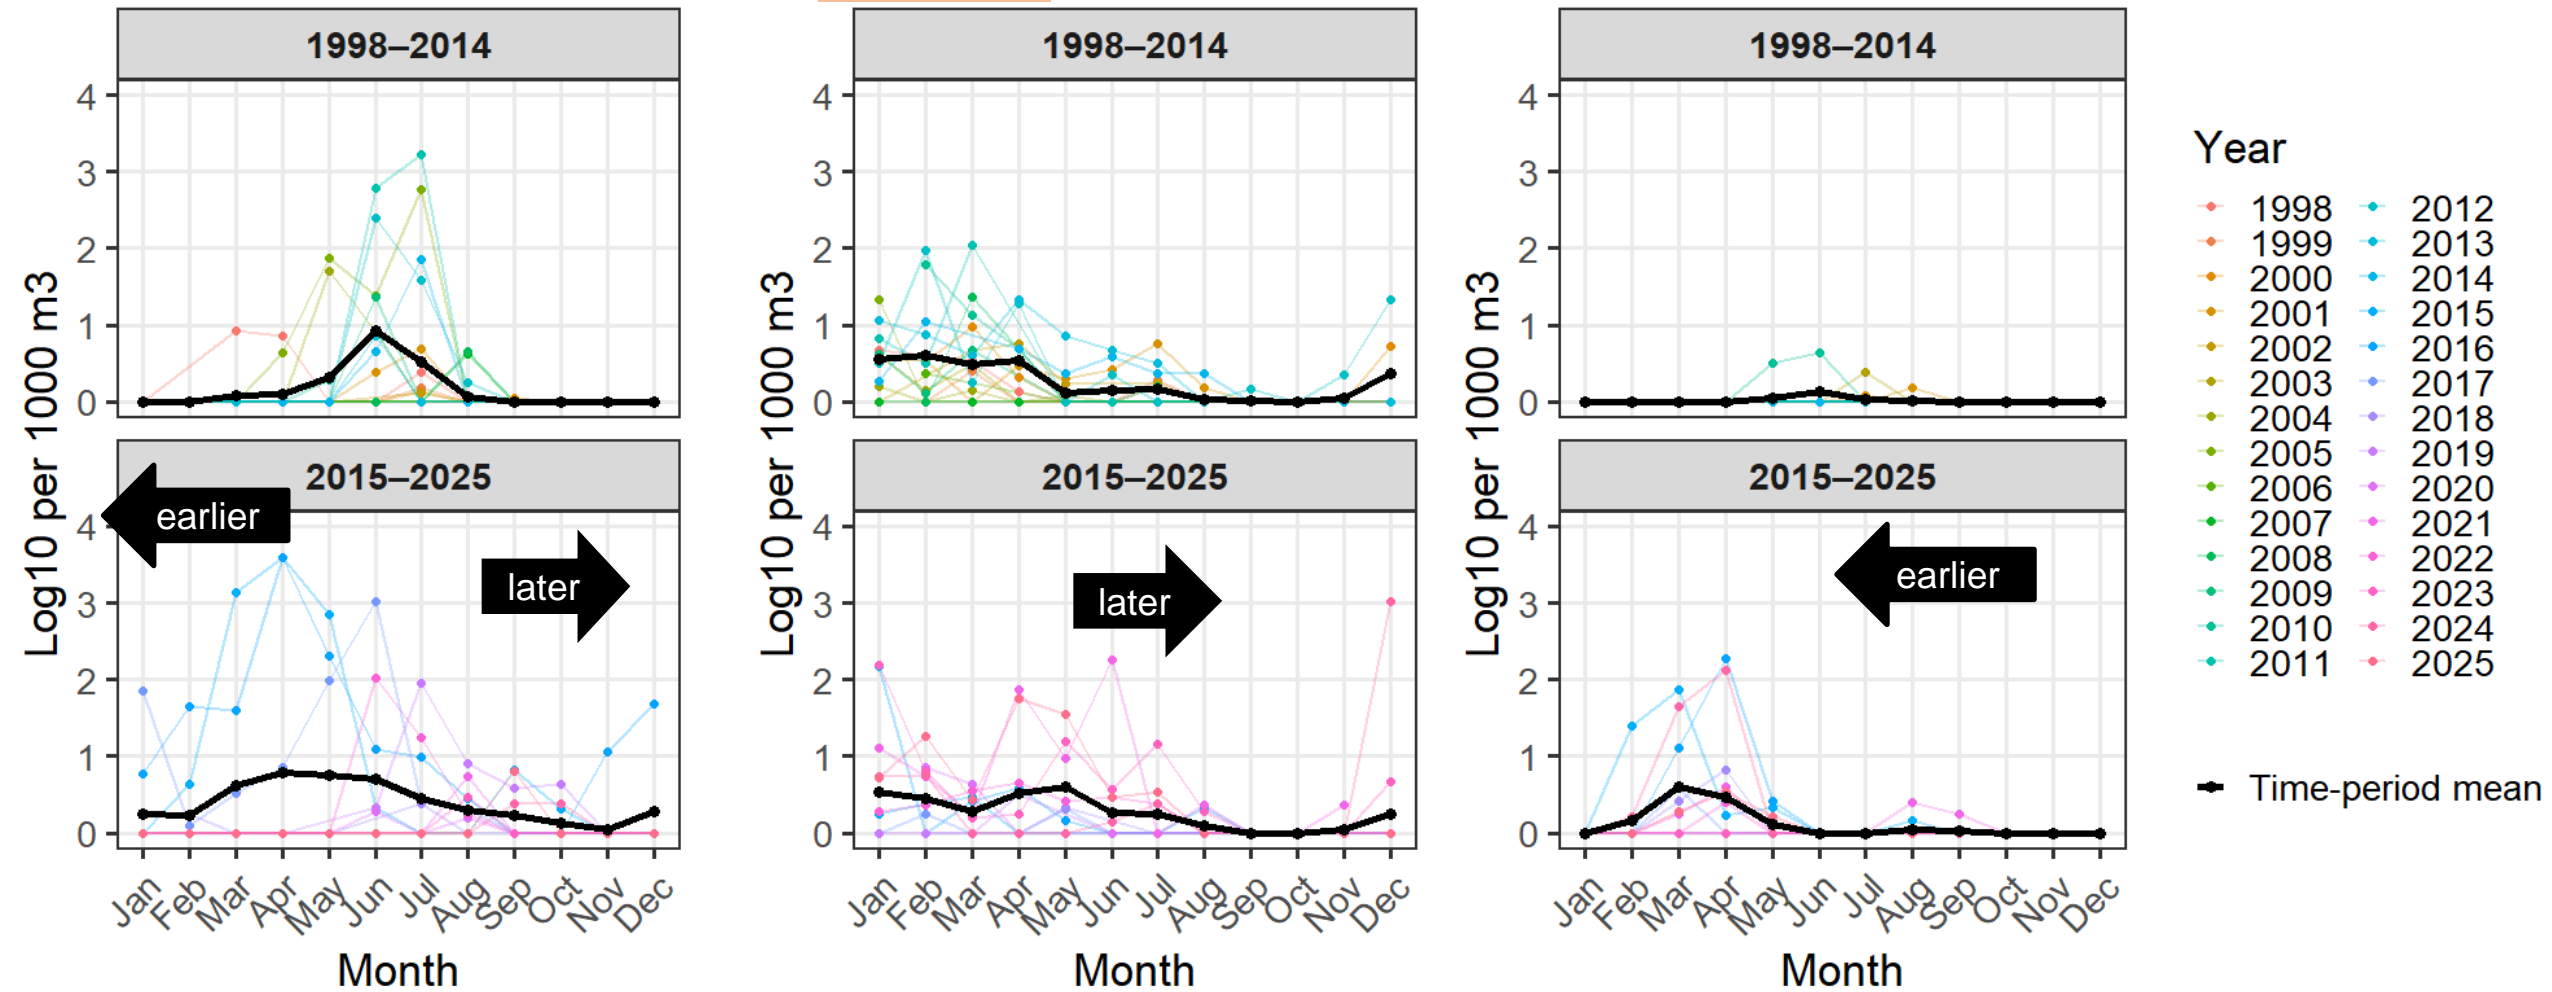

Extended presence of larvae in the NCC between the two time-periods suggests spawning conditions/ larval success has been better since 2015

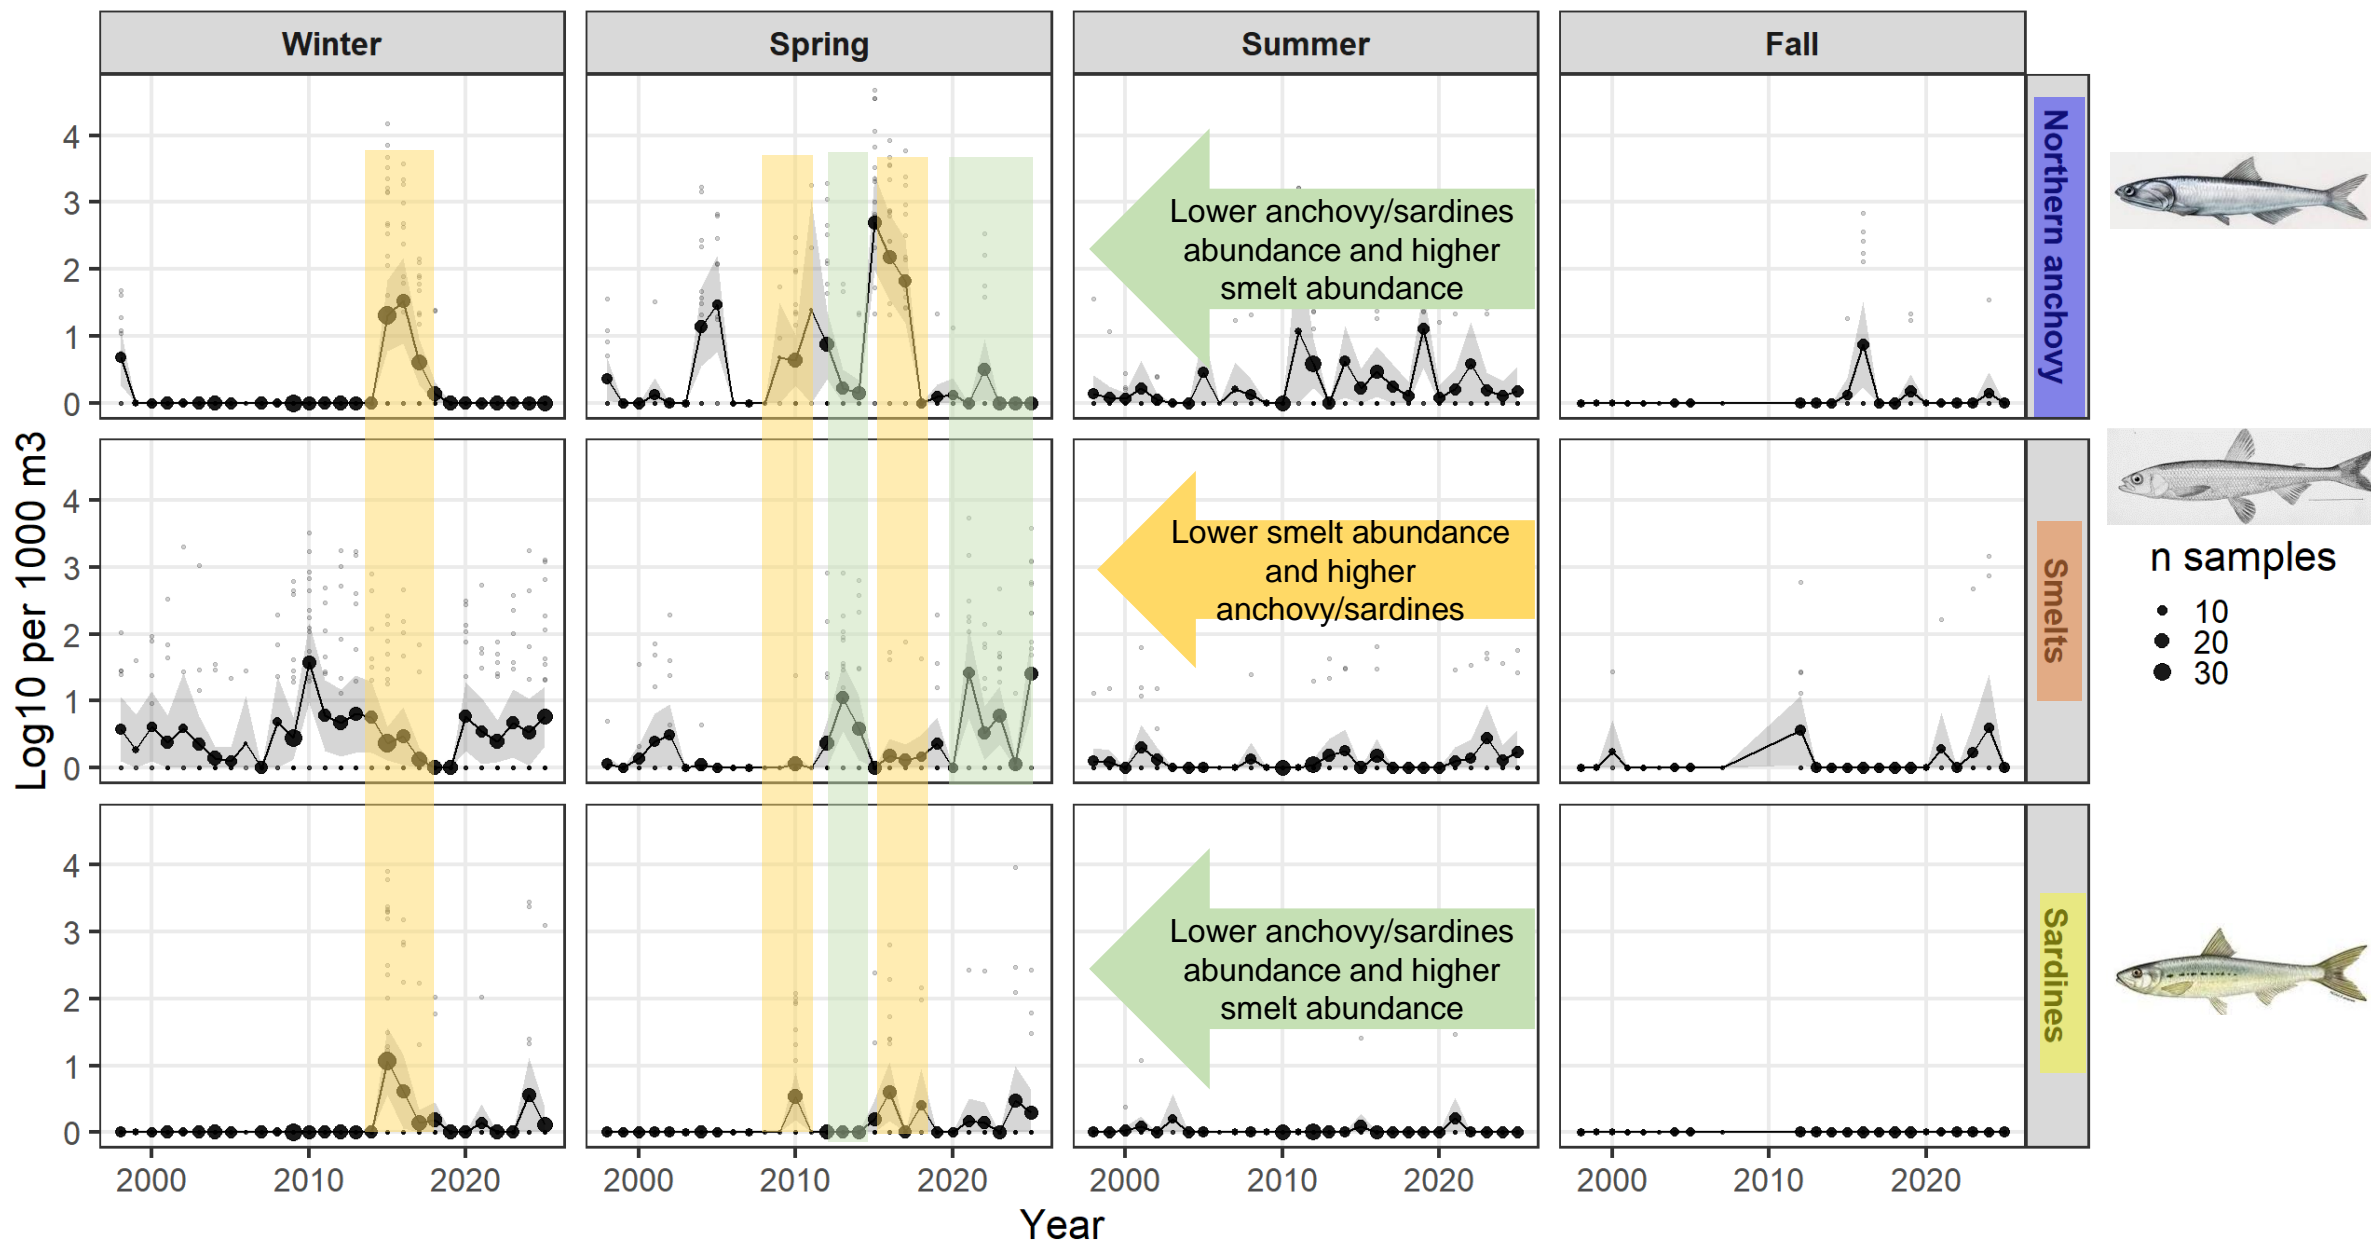

n_anchovy

smelts

sardines

Alternating changes in abundance between anchovies and smelt larvae early in the year: NH line bongo net 1998-2025

Larval SPF occurrence in the environment is largely structured by station temperature and not salinity (or chlorophyll)

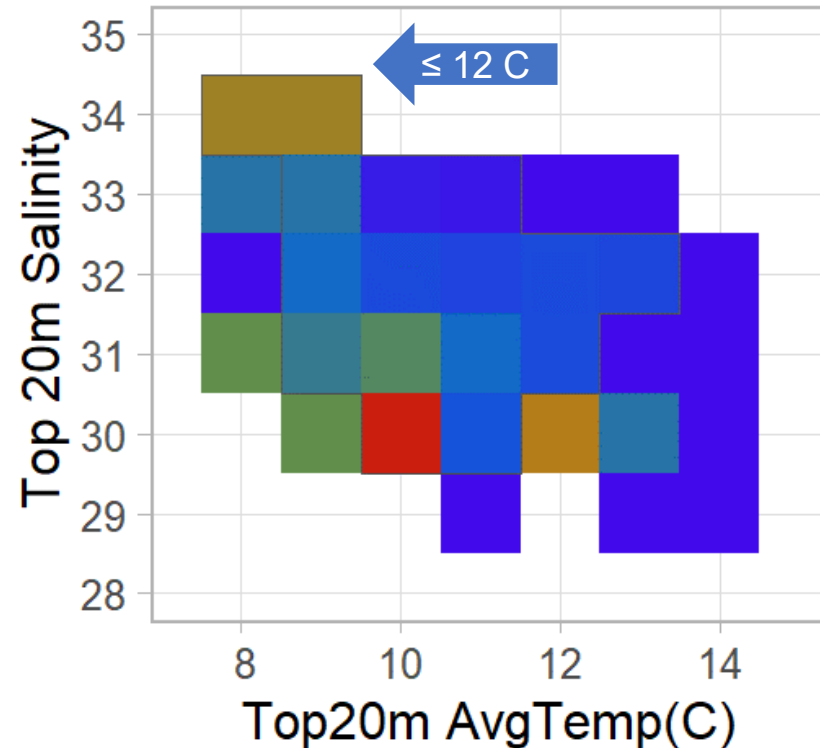

Probability of occurrence

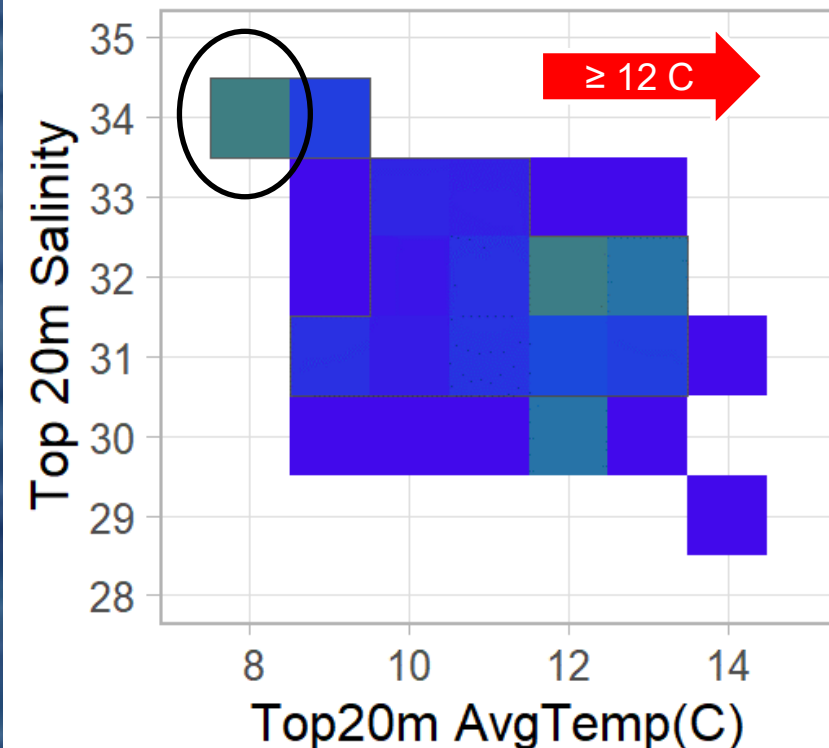

N anchovy (All months; 1998-2025)

Smelts (All months; 1998-2025)

P sardine (All months; 2015-2025)

Juvenile SPF and salmon diets: May trawl (30 m by 20 m) with a fine-mesh liner

Pacific sand lance

Smelt

Sardine

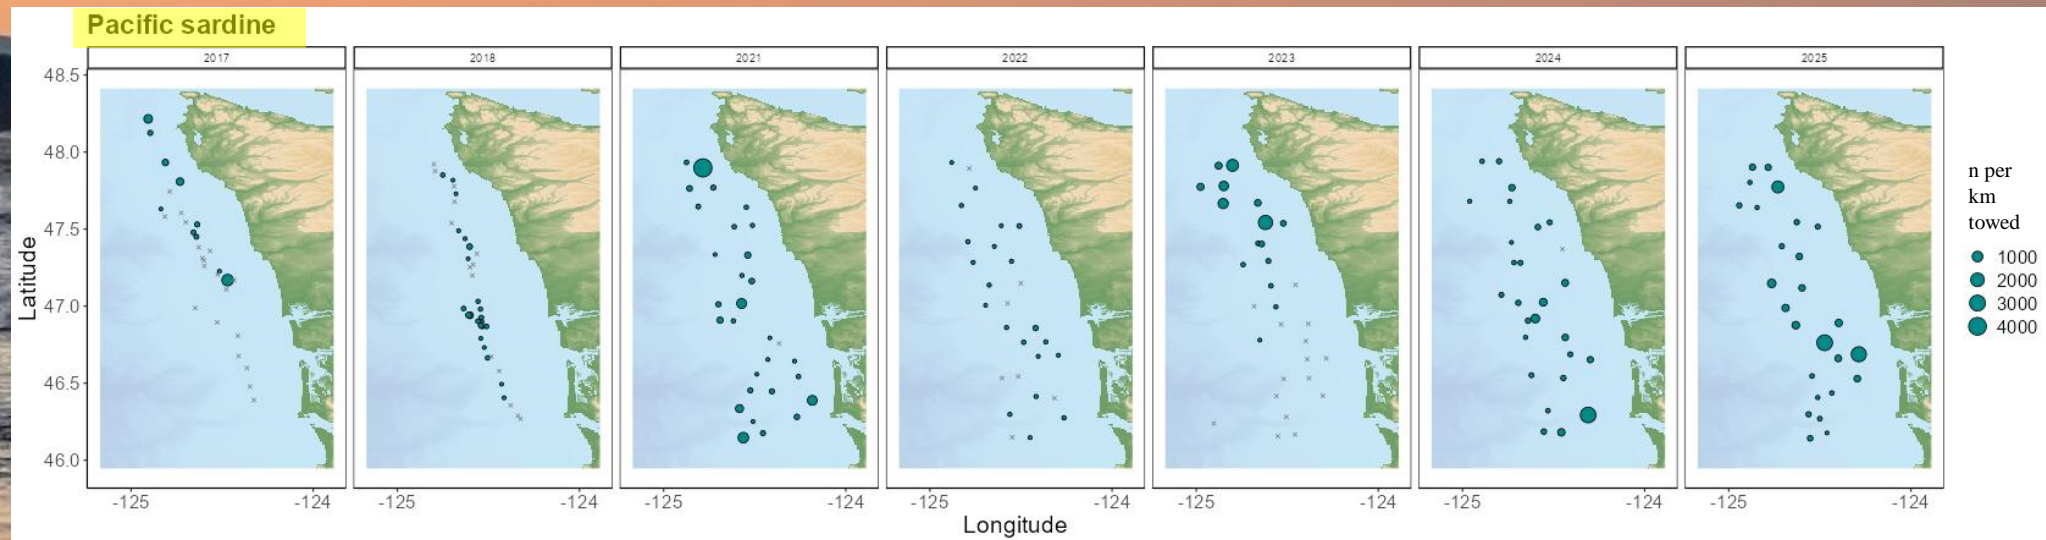

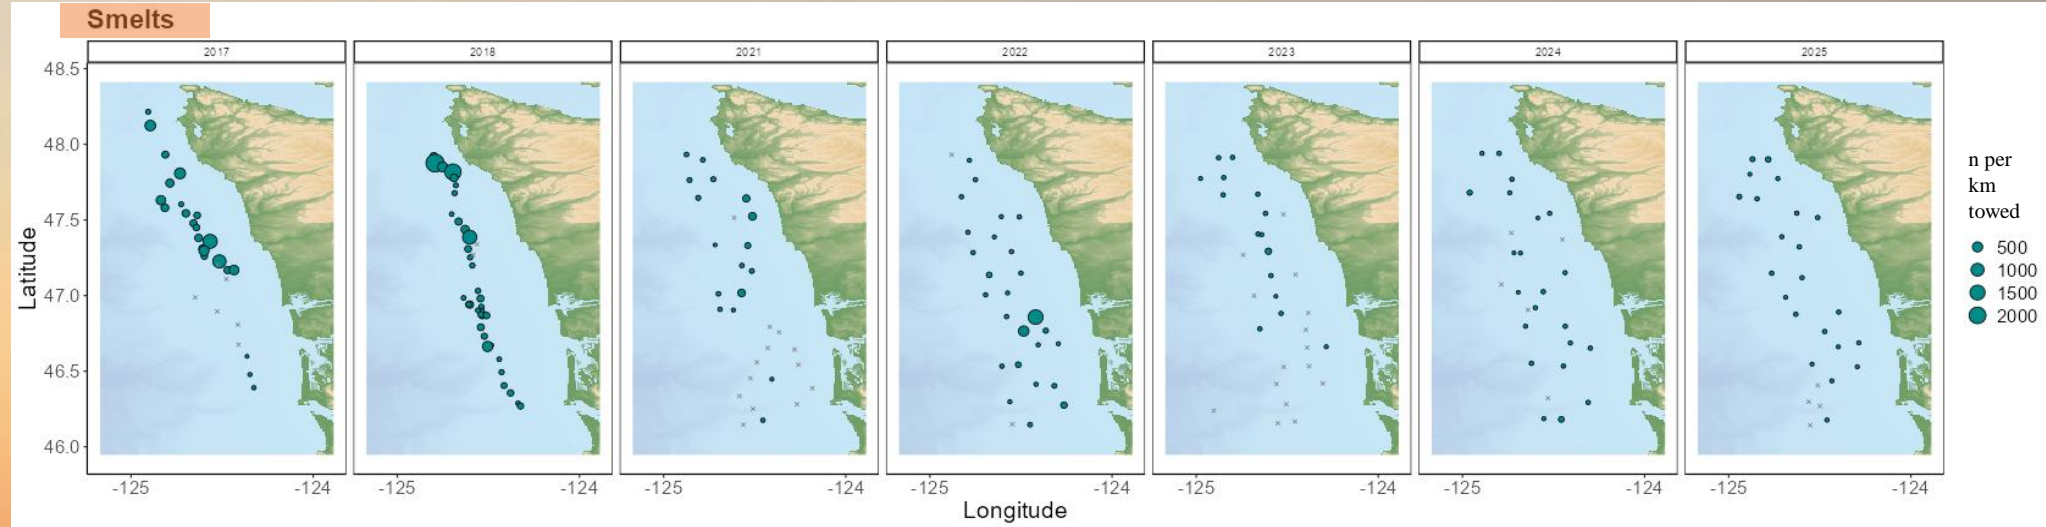

Northern ronquil

SPF (smelts and sardine) make up over half of the juvenile fish biomass in the upper 20 m in May, along with other juvenile groundfish

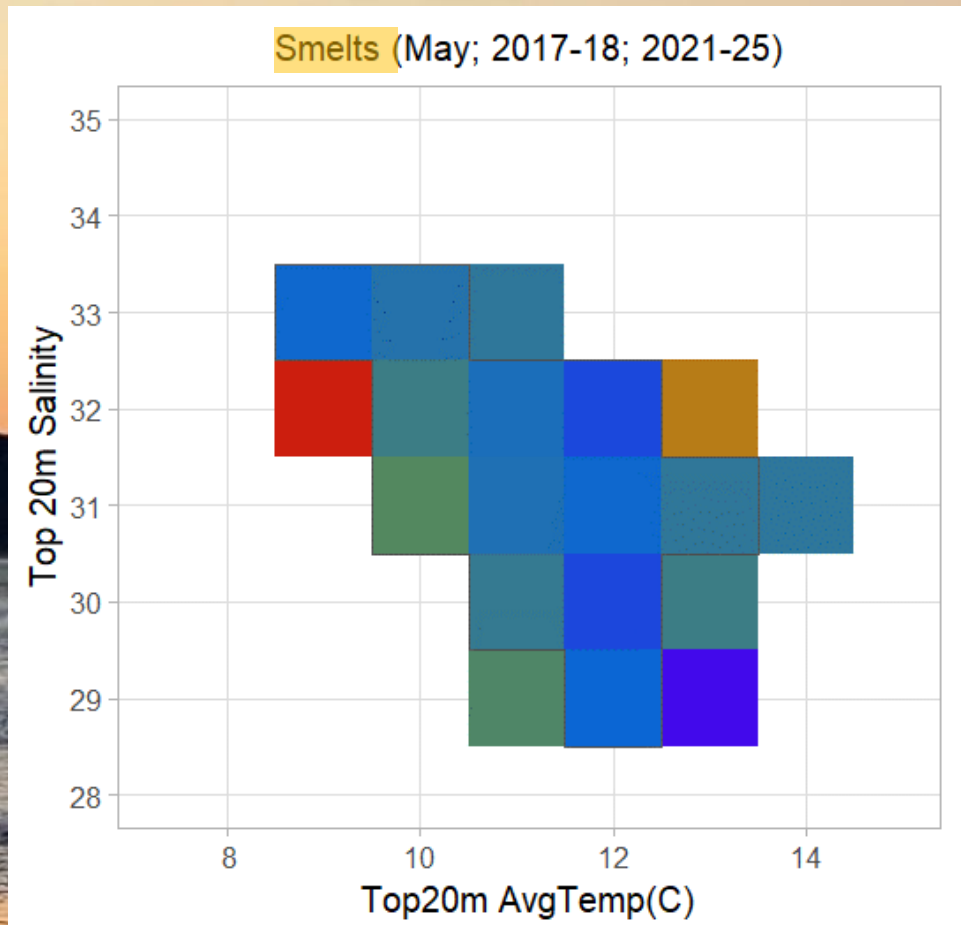

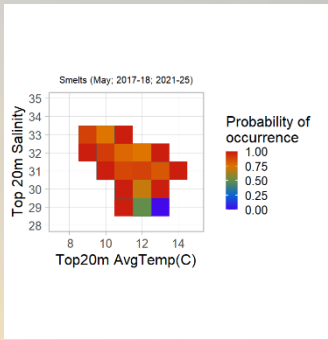

Where are the juvenile northern anchovies?

Larval & juvenile smelts and sardines are caught in May along the coast of Washington

In May, juvenile SPF CPUE did not show a relationship with temperature. There was a weak relationship between higher CPUE of juvenile sardines and salinity

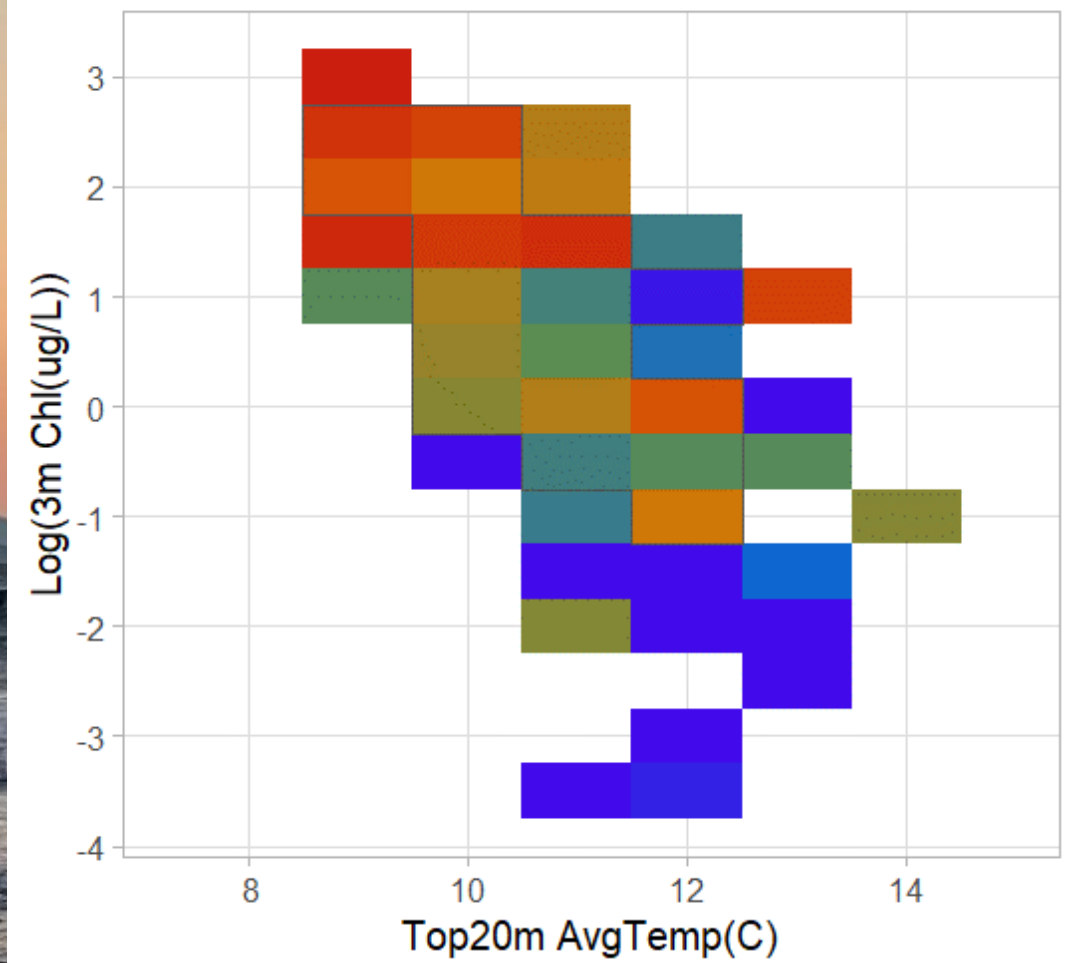

Both juvenile smelt and sardines showed increased CPUE in association with higher 3-m chlorophyll

Smelts (May; 2017-18; 2021-25)

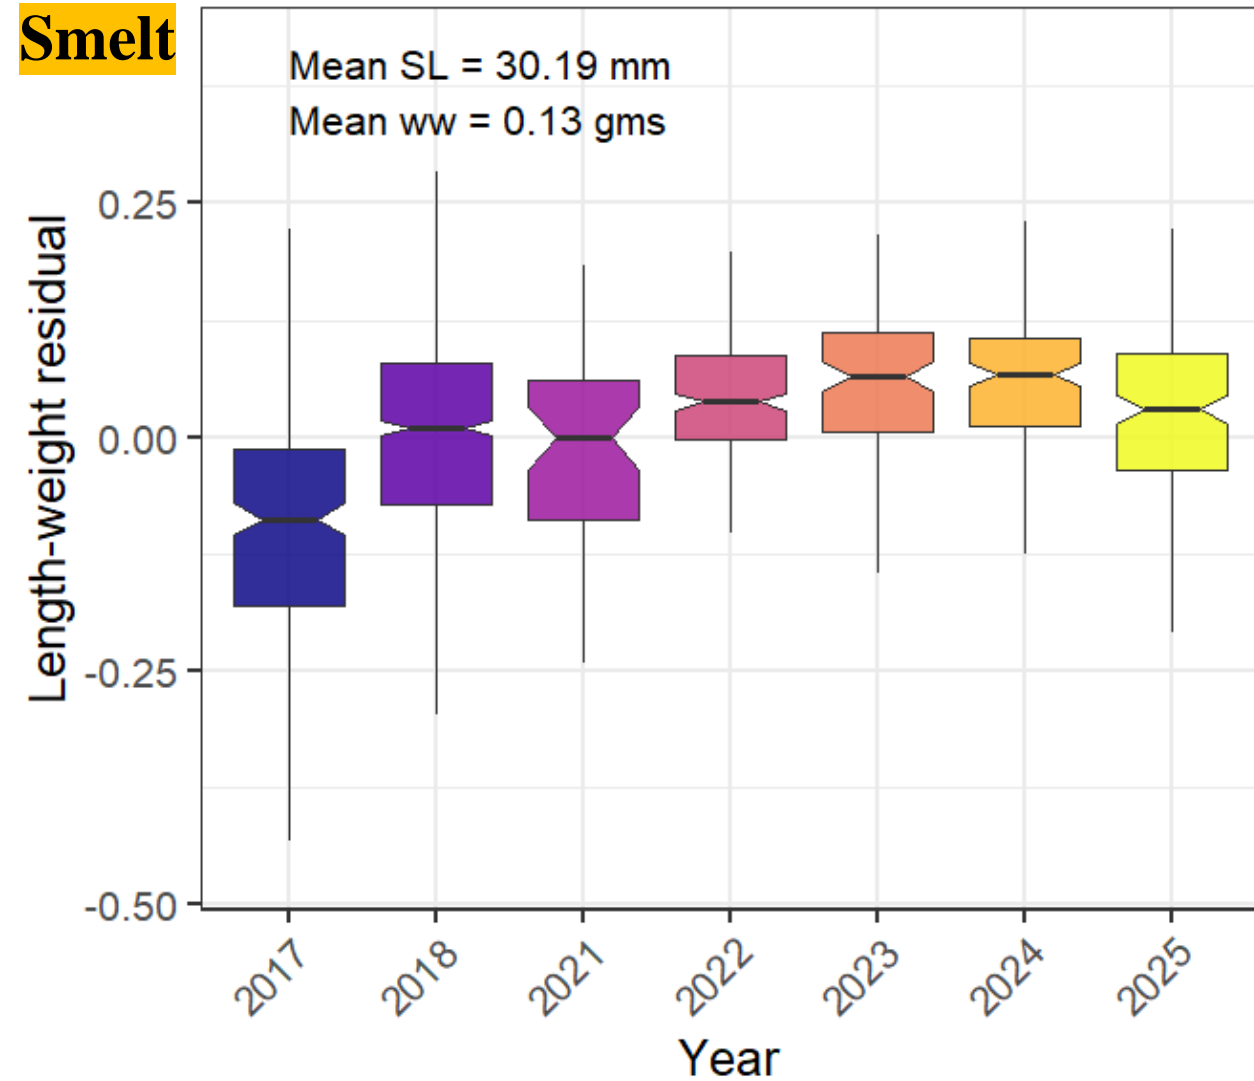

P sardine (May; 2017-18; 2021-25)

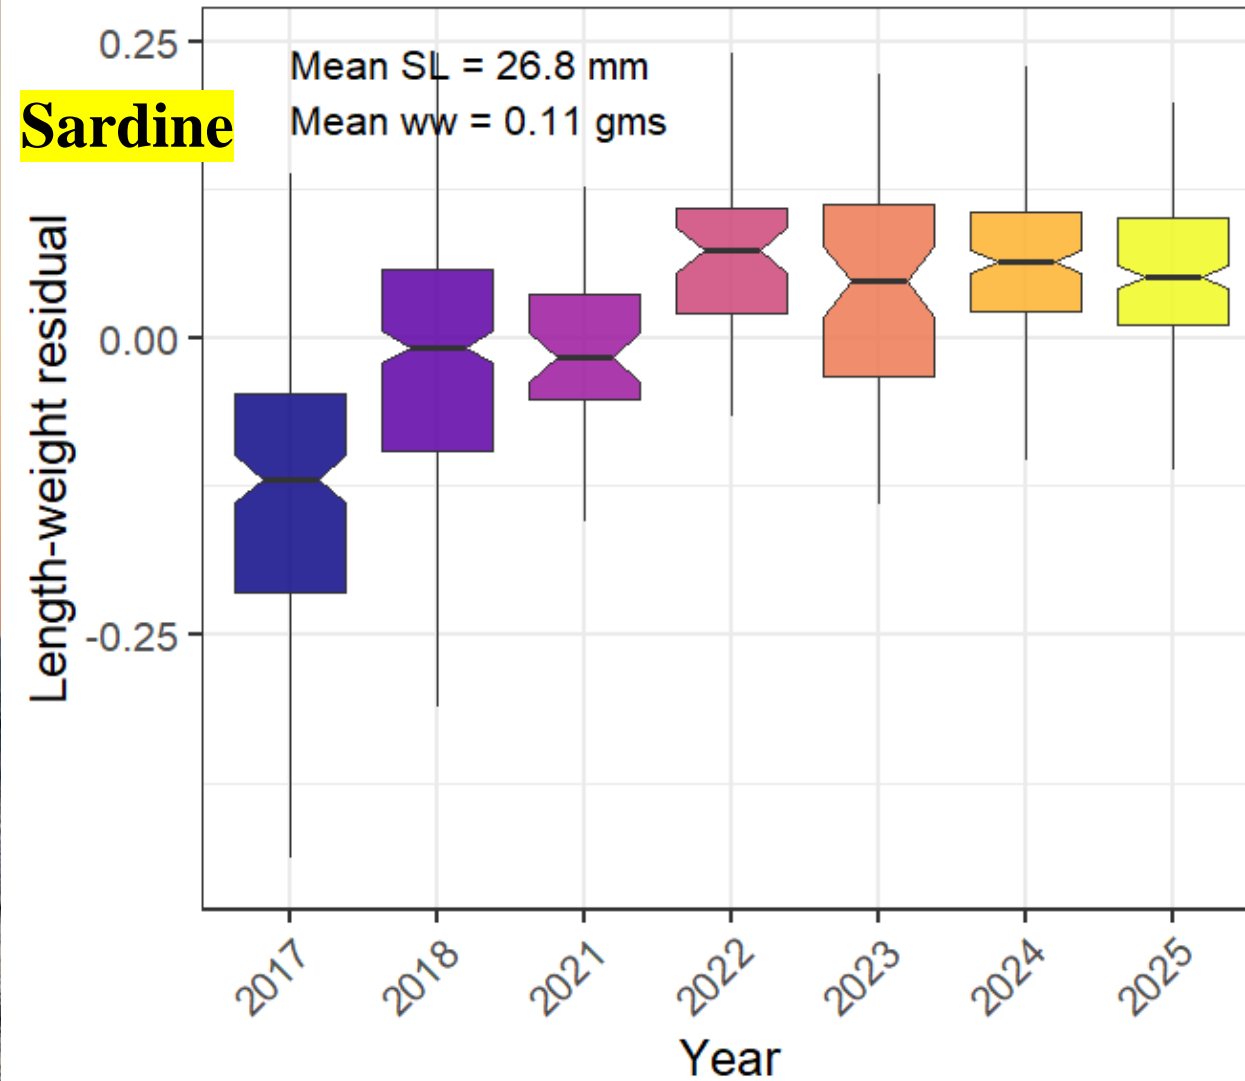

The condition of juvenile smelt and sardine followed a similar interannual pattern: thin in 2017 and better condition 2022-2024/5

Smelt

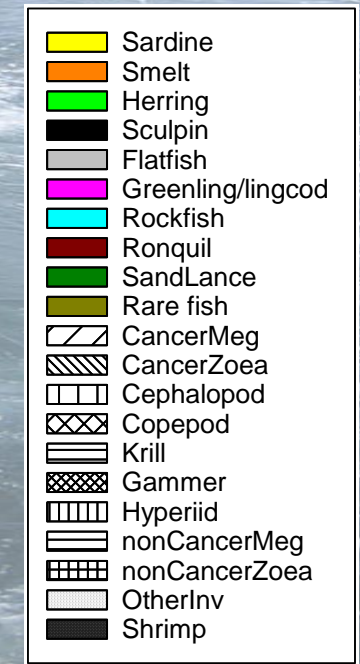

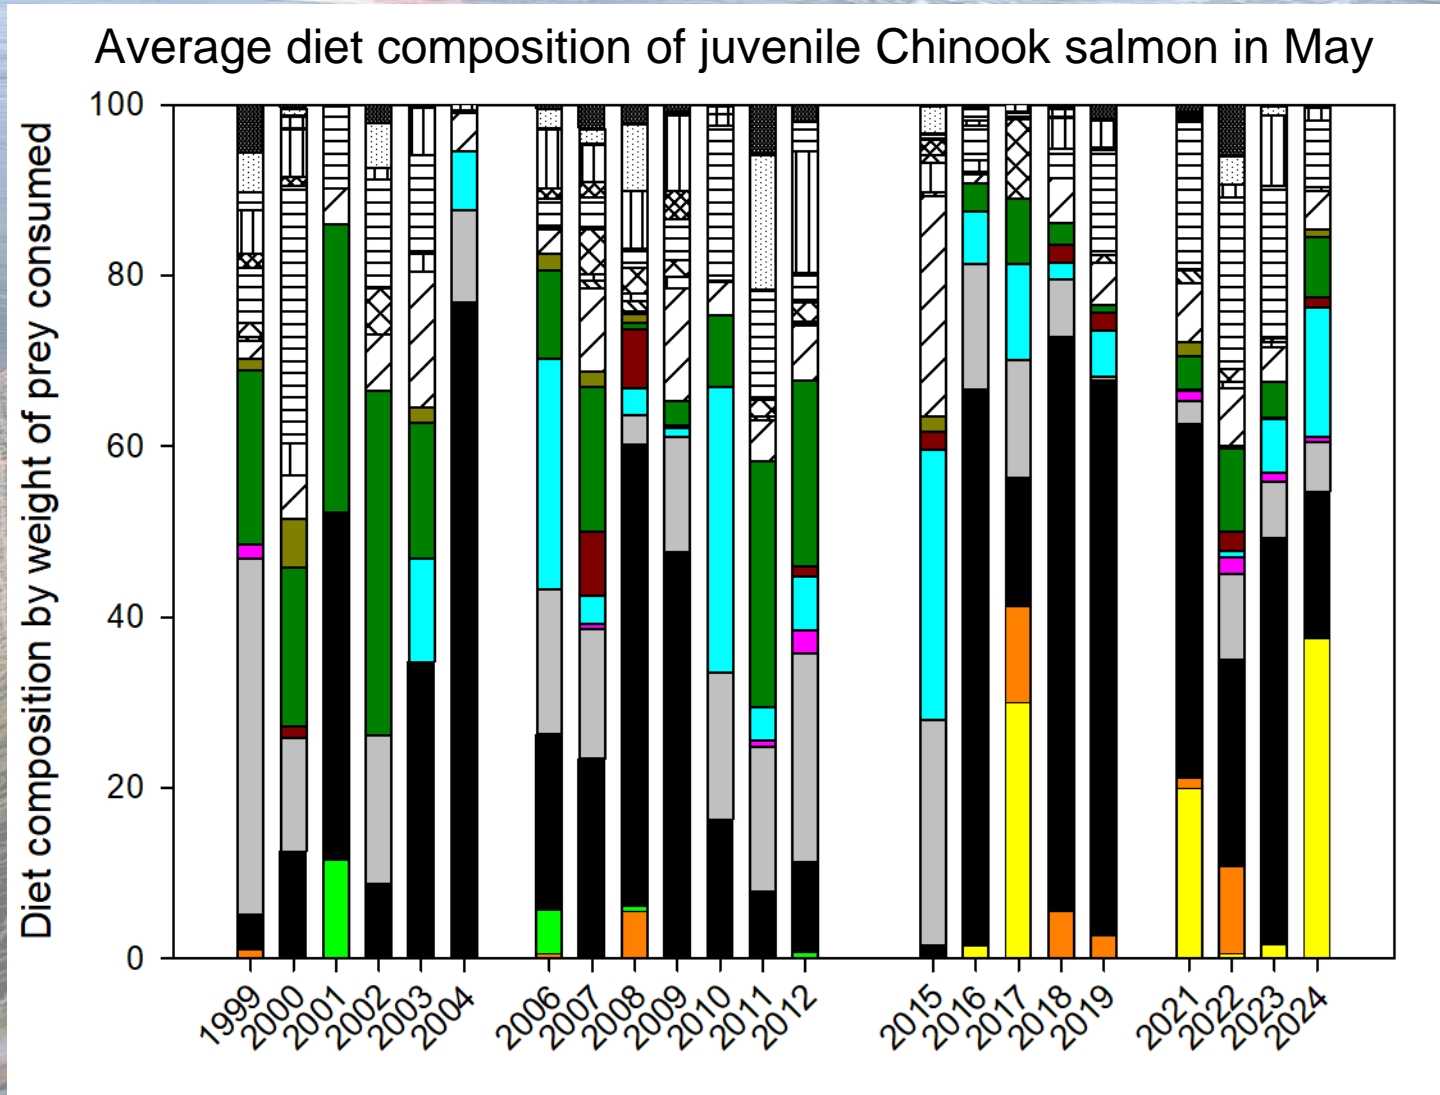

Sardine

Juvenile Chinook salmon are highly piscivorous when they enter the ocean

Sardines were not observed in the diets in 1999-2015, but in 2017, 2021 & 2024 **sardines** were an important prey item for Chinook salmon

Smelts are not generally an important prey

Anchovies have not been consumed in May

In summary:

- Recent warm ocean conditions is correlated with extended SPF larval presence in the NCC
 - Smelts and sardines have increased in size/condition; anchovy did not
 - Temperature and chlorophyll influenced SPF occurrence and CPUE
 - Sardines emerged as an important salmon prey in recent years

Thanks to all the research scientists within Oregon State University and NOAA fisheries, the captains and crew of the many research and fishing vessels. Funding was provided by Bonneville Power Administration and NOAA fisheries.
