Ecologists, managers, & stakeholders often ask:

How many individuals?

Why are they there?

# Species Distribution Models

# Species Distribution Model

Species data

Covariates

**What covariates?**

**What model is best?**

Statistical or mechanistic model

Predictions

# Model Comparison

3x3 factorial design

## 3 Models

Boosted Regression Tree (BRT)

Generalised Additive Model (GAM)

Vector Autoregressive  
Spatiotemporal model (VAST)

## 3 Covariate configurations

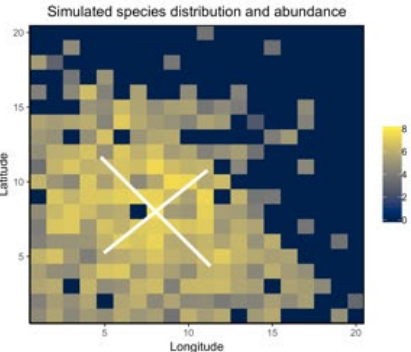

Spatiotemporal

Environmental

Spatiotemporal & Environmental

# Results: Spatial Predictions

Simulated Truth

Environment is missing

Space & time is missing

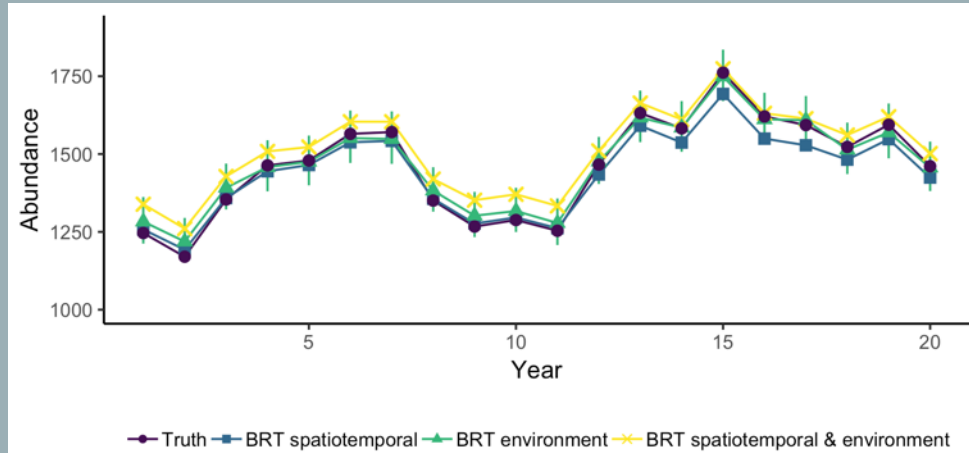

All covariates included

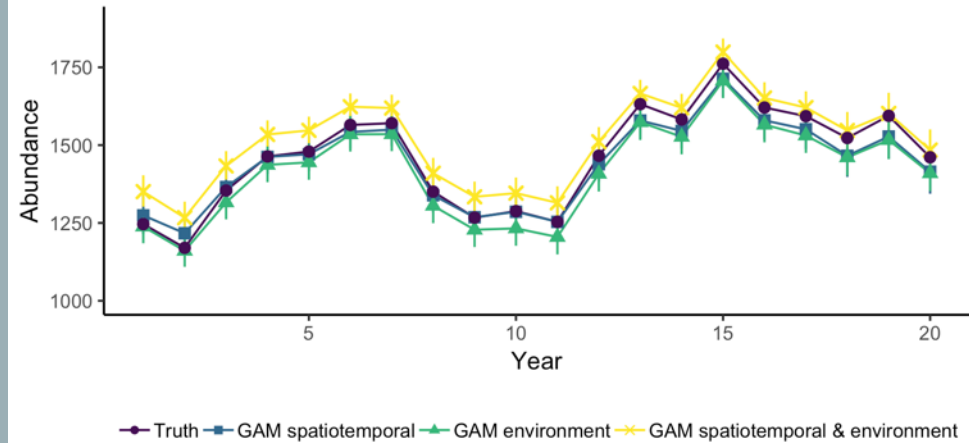

# Results: Time-series of abundance

BRT models →

GAM models →

All models do well but VAST is best →

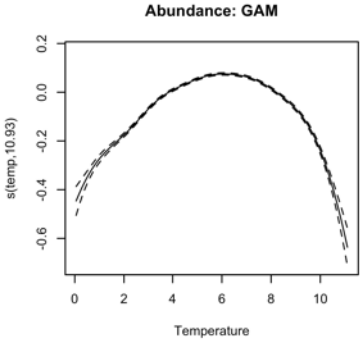

Results:  
Model response curves

BRT models:  
regression tree splits

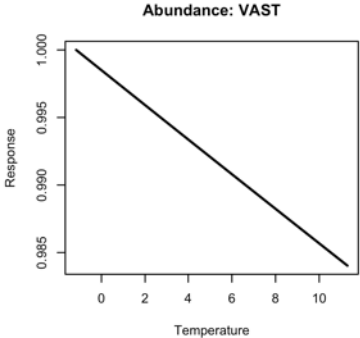

Truth →

GAM models:  
spline smoother

VAST models:  
quadratic functions

# Simulation Summary

- VAST was best for estimating abundance
- Non-linear models can accurately represent environmental relationships
- Models including both environmental and spatiotemporal covariates are best

**Limitation: Ecological  
Forecasting**

# Why predict the future?

Understand the world

Inform decision making

# Decisions change across time-scales

Decision Lead Time

0-10 days

Weeks to Months

Decades to Centuries

# Decisions change across time-scales

Decision Lead Time

Forecasting ecology relies on ecology being predictable

# Where can ecological predictability come from?

- Advection

Shin-ichi Uye ICES CM 2014/3064 A:01

# Where can ecological predictability come from?

- Advection
- Phenology

# Where can ecological predictability come from?

- Advection
- Phenology
- Life-history

- Life-history
- Persistence
- Response to the environment

# What about highly migratory species?

Basin-scale migrations

Memory? Age?

Regional-scale movements

Environment? Prey availability?

# What about highly migratory species?

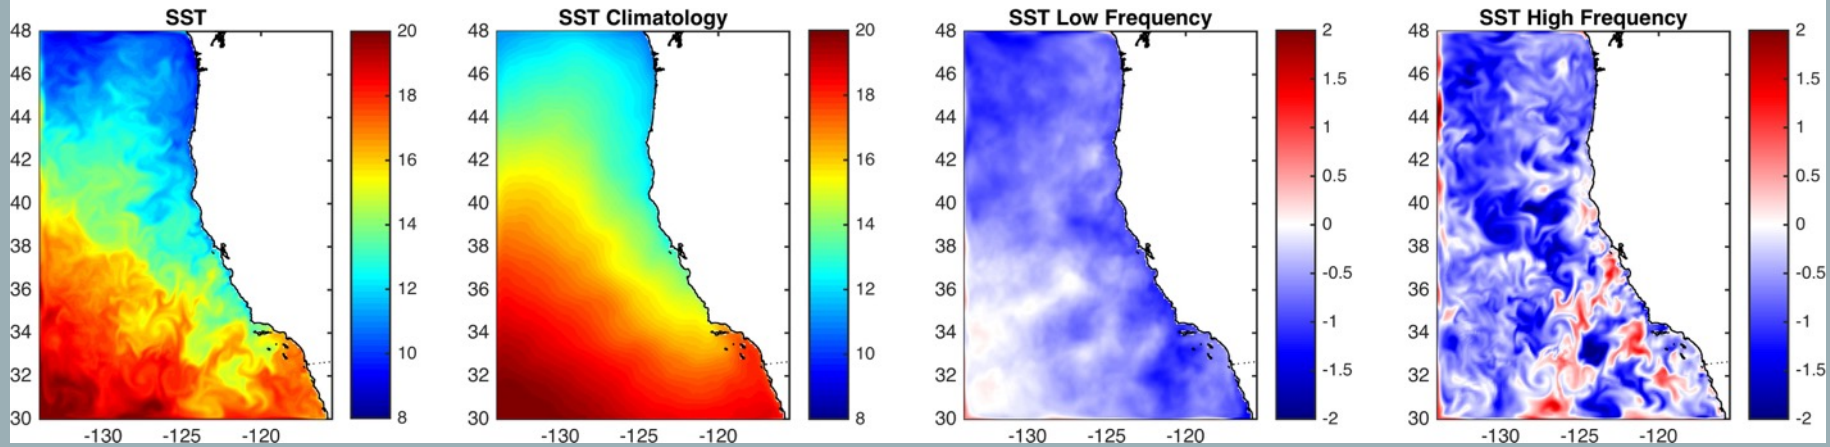

At what scales does ecology respond to the environment?

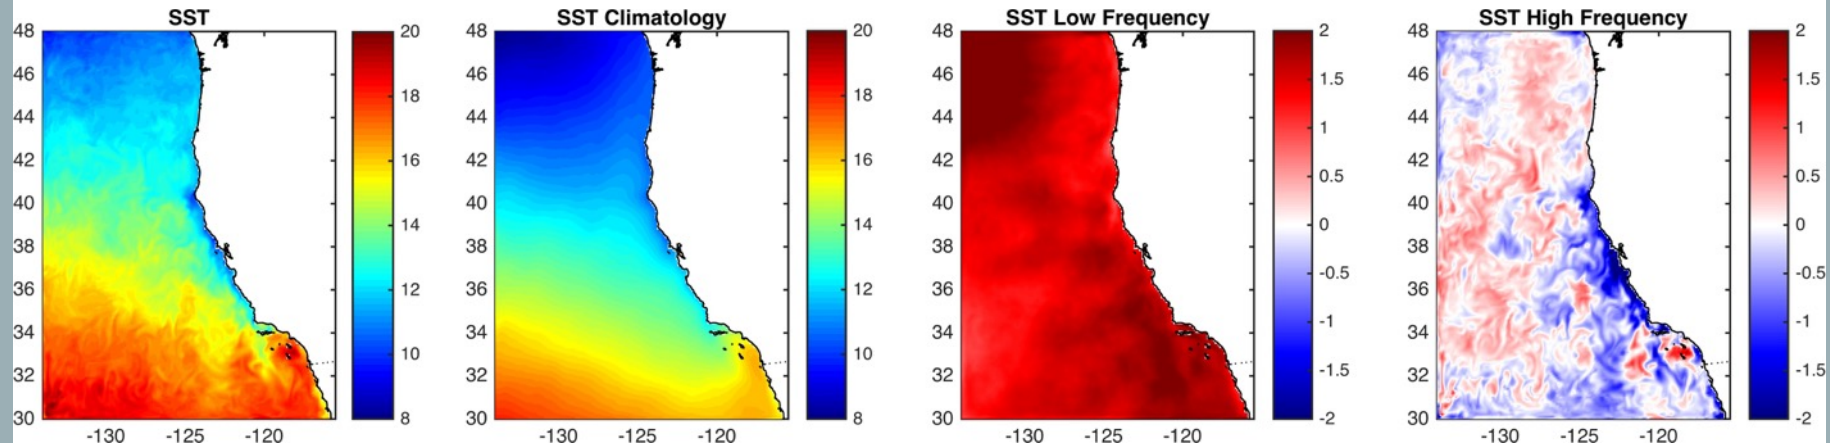

Test using temporal decomposition

# Temporal Decomposition of SST

23 November 2007

15 April 2015

# Temporal Decomposition

Native Resolution

23 Nov 2007

15 Apr 2015

Climatology

Low Frequency

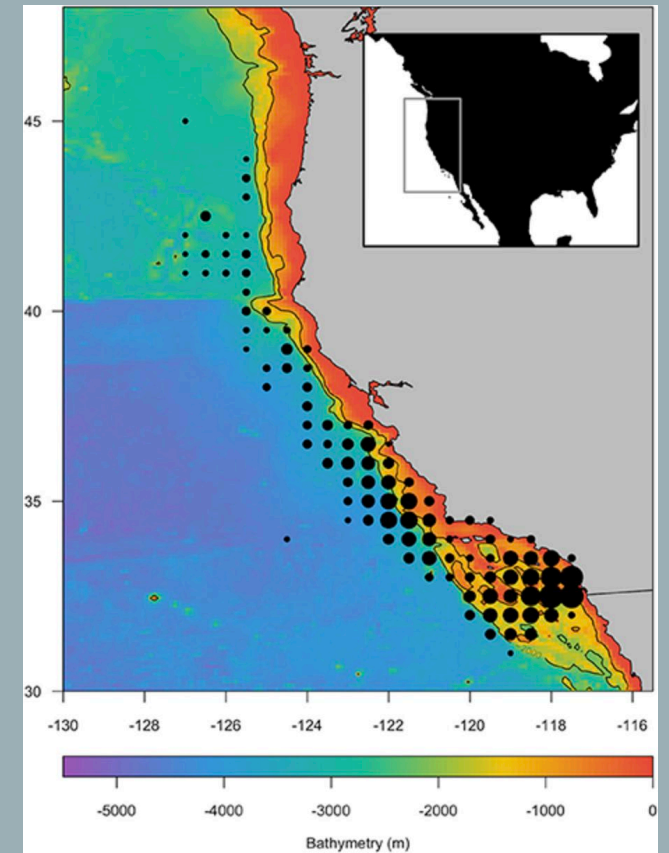

High Frequency

SST

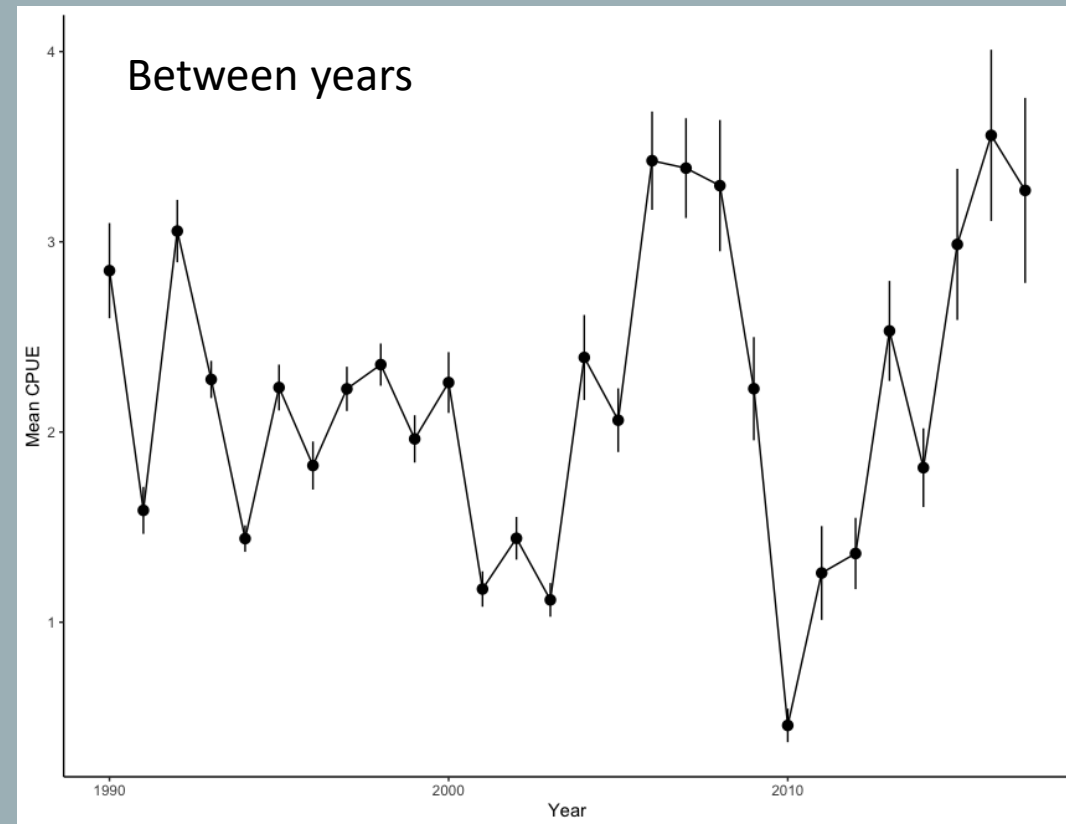

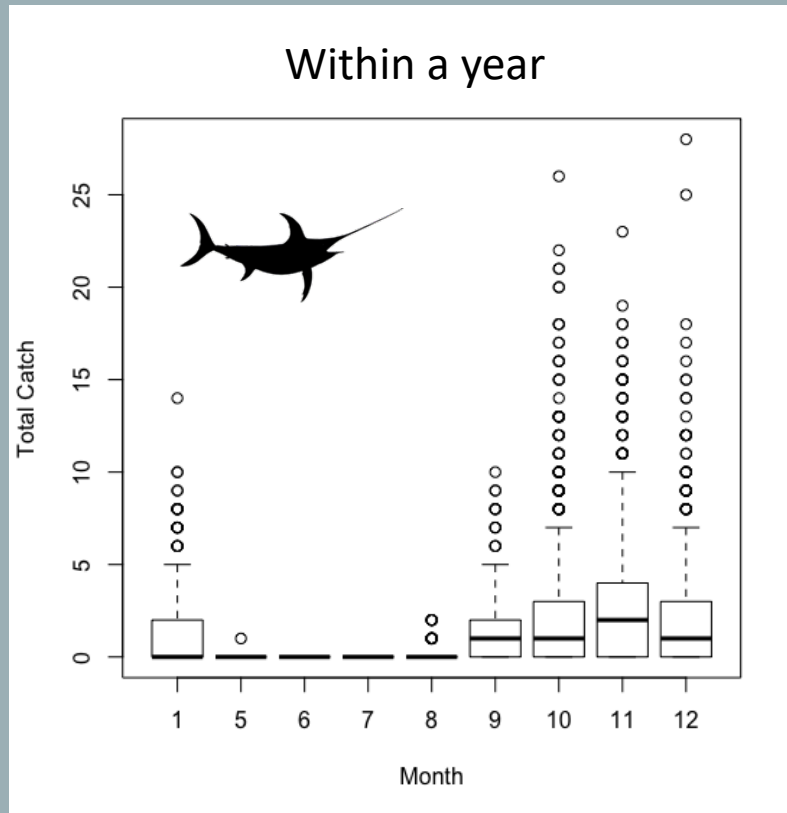

# Case Study: Swordfish in the California Current

# At what temporal scales are swordfish responding to?

# Species Distribution Model

## GAM Covariates

MLD  
SST  
Chl-a  
Gear soak time  
Trip number (random)  
Lunar illumination

Note the fine-scale features  
Forecasts can't resolve this

## Predicted Abundance

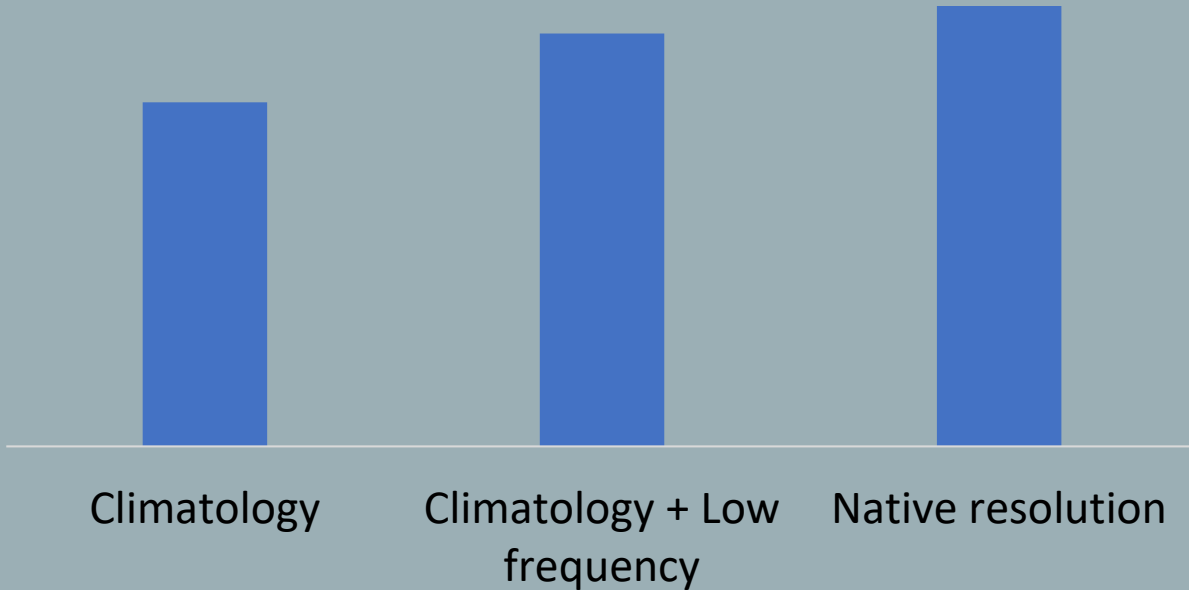

Climatology + Low frequency is the dominant signal

# What about predictive performance?

Expected Relationship

- True for model fit
- BUT no consistent relationship for predictive performance
- Predictability comes from the climatology

# What this means

- Swordfish distribution and abundance most strongly associated with the climatology
- Don't expect predictability of swordfish based on climatology AND skillful forecasts of environment
- Gives us a better understanding of the sources of skill for ecological forecasting

# Next Steps

- Test concepts on more species & tracking data
  - Tracking data is more sensitive to ephemeral and mesoscale features
- Retrospective seasonal forecast
