

Shifts in species abundance of sardine fisheries in southern Philippines: early signs of vulnerability to climate change?

Asuncion de Guzman, Cesaria Jimenez, Angelo Macario, Juliet Madula and Jayrald Santamina

Mindanao State University-Naawan Philippines

Background: the ICE CREAM Program

- 3-year collaborative climate research program funded by the Philippine government
- Utilizes pressure-stateresponse framework to analyze CC drivers and propose interventions
- 8 project components;6 research institutions

Department of Science and Technology (DOST) - Philippine Council for Aquatic and arine Research and Development (PCAMRD)

Background: Coastal climate regimes of the Philipines

- 10 coastal climate typologies based on rainfall data
- Coasts around Mindanao island classified into 4 climate types ~ highly variable

Western Philippines Rainfall peaks occur during the southwest (SW) monsoon Type II, III & IV - pronounced wet and dry periods; Types II & III have higher rainfall during wet periods as compared with Type IV; Type II has a seasonal SSH signal Type V- Generally low rainfal throughout the year but with peaks mostly in the SW, similar to Type VI in Southern Phil . Generally low rainfall distributed throughout the year . Type VI-rainfall peaks generally occur during the southwest monsoon, except during La Nina; higher SSH signal than Type V David, et al. unpub. Type VII—rainfall peaks generally occur during the northeast monsoon, enhanced during La Nina

Northern Philippines

Type I: rainfall peaks occur during the southwest mon-

soon, visibly reduced during

Eastern Philippines Rainfall peaks occur during the northeast (NE) monsoon

Type VIII & IX—generally

Type VIII—peaks occur

mid NE monsoon Type IX peaks occur early NE monsoon Type X-generally lower

higher rainfall, enhanced during La Nina

Vulnerability of Philippine coasts

- Marine biogeographical basins of Philippines integrated with coastal climate regimes
- Differential vulnerability to NE & SW monsoons and tropical storms
- ICECREAM project sites across Phil. Archipelago
- Weather/CTD stations in at least 6 locations

Asia's Stormiest

19 of 39 TS during
 Pacific typhoon
 season hit the
 Philippines in 2009

Source: Wikimedia Commons, 2009

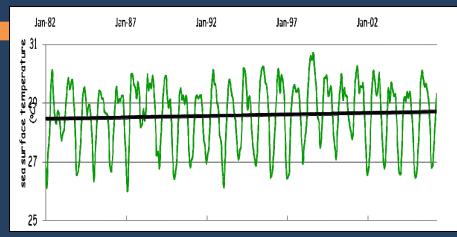

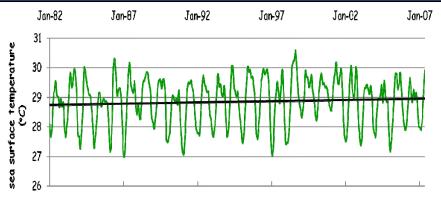

SST along eastern Phil. seaboard

Source: PacSEA project (2007)

Both sites show an overall increase of 0.5 °C from 1982 to 2007

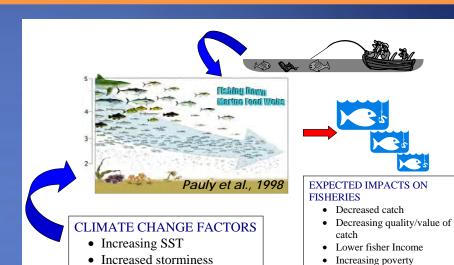

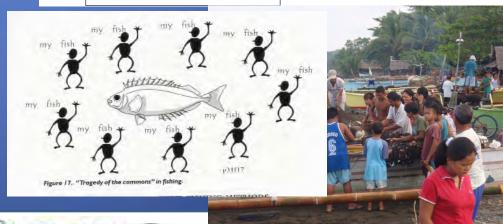

Project 6: Coastal Fisheries

- Component looks into potential effect of CC on production variability of important fish resources
- Drivers: Climate or Fishing?
- Human-environment synergy: impacts on fisheries and marginal livelihoods

Sea level rise

Increased precipitation

Sardine as climate proxy

- Indian oil sardine Sardinella longiceps forms a large part of small pelagics production of nearshore fisheries
- Sardine is associated with high productivity areas; upwelling zones
- Can be a proxy to changing climate – impacts on spawning & recruitment

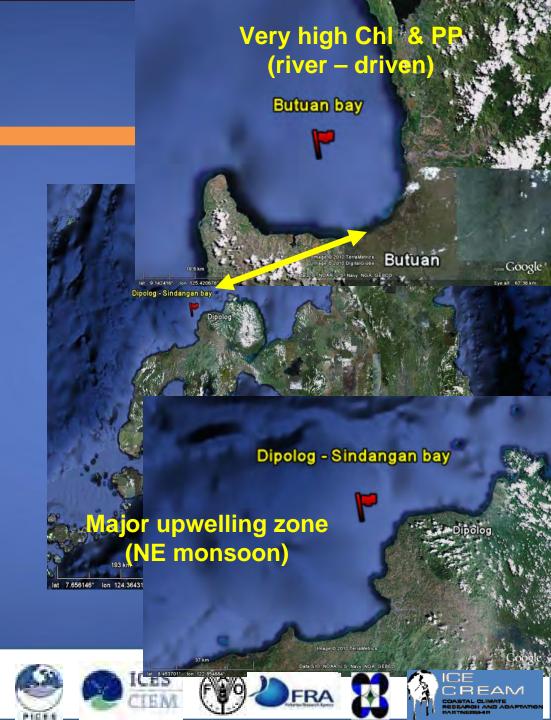

Methodology

- Monitoring of landed catch in two bays along the East-West gradient (Mindanao Is.)
- Data available on May
 2009-March 2010
- Comparison between upwelling- and watershed-driven productivity

Methodology

- Fish landing surveys
- Monitoring of catch and effort of major gears
- Monthly length-frequency measurements (future popdyn parameters)
- Sex ratios, gonadal maturity determination

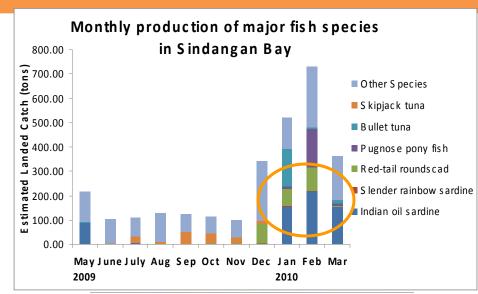

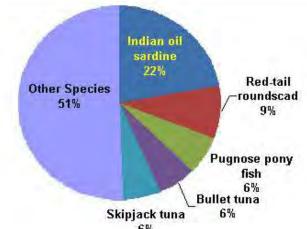

Preliminary Results: Sardine production in Sindangan Bay

- Landed catch of Indian oil sardine Sardinella longiceps = 625 t
- Represents 22% of total landed catch of 2,856 t
- The rainbow sardine, Dussumiera elopsoides, mixes in very small proportions
- Abundant juveniles in Dec/Jan

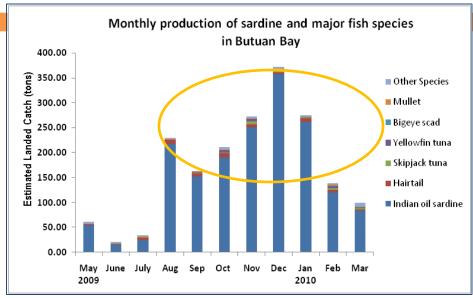

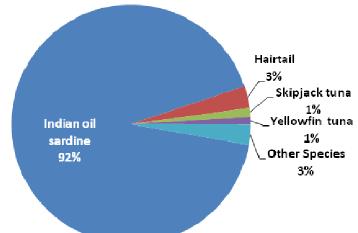

Preliminary Results: Sardine production in Butuan Bay

- S. longiceps (1,732 t)
 dominates landed catch
 (1,881 t) from Butuan
 Bay in same period
- 2000 assessment:
 dominant species was S.
 melanura presently
 caught in small amounts
- Spawning: Dec-Feb

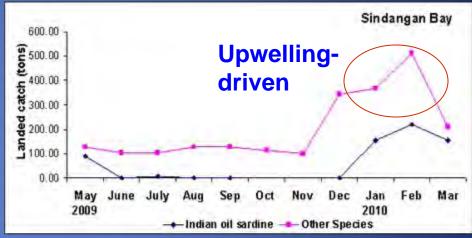

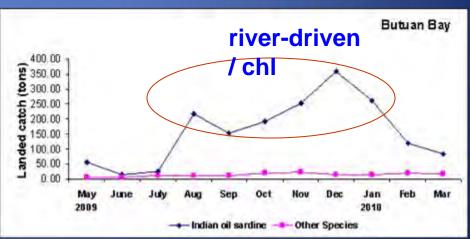

Shifts in abundance: climate related?

- Apparent asynchrony in abundance of sardine in two bays
- Hypothesis:
 - Seasonal recruitment oscillations (upwellingdriven vs chl or nutrient variability)
- Fisher perception: delayed appearance of juveniles in SB than in past years

Shifts in abundance: Other potential drivers

- Migration
 - Linear shifts (inshoreoffshore; shallow-deep; bay-to-bay gradients)
- Overfishing
 - Increase in demand for fresh sardine to supply post-H facilities in Sindangan Bay
 - Consequential in fishing effort

Growth of sardine postharvest industry in Sindangan Bay

- High annual production motivated rapid growth of post-harvest industry
- 20 sardine bottling companies (small, family owned enterprises)
- Low sardine catches offset by exporting sardine from other areas (large operational costs)

Generalizations

- More questions than answers
- Tropical, small-scale fisheries are high biodiversity systems
- Vulnerable to overfishing
- Experiencing 'fishing down the web' phenomenon
- Need for adaptive FM to ensure food security & income

ICECREAM's goal and challenges

- ICE CREAM is a "newborn" in climate research
- Goal: to contribute to CC and Fisheries science in data-poor systems (with no long term time-series data)
- Challenge: attribution of changes or variability in fisheries systems to Climate – disentangled from overfishing and other drivers of stock changes

Next Steps...

- Backward and forward time series C/E data
- Link fisheries production patterns with ocean/climate data from (IC Component 2)
- Need to disentangle CC and fisheries effects
- Study spawning/recruitment patterns and possible correlations with SST, salinity, etc

Man must eat...but fish has to live, too!
