

NEREUS
PREDICTING THE FUTURE OCEAN

Nereus Program: Predicting the Future Ocean

Villy Christensen & Yoshitaka Ota, University of British Columbia

Jorge Sarmiento & Charles Stock, Princeton University / GFDL

Patrick Halpin, Duke University

Louisa Wood, UNEP World Conservation Monitoring Centre

Carl Folke & Henrik Österblom, Stockholm Resilience Centre

Will there be fish for coming generations?

- ❖ Fisheries have collapsed across the globe linked to overcapacity of fishing fleets
- ❖ Predictions of future fisheries are contradictory, and build on very incomplete science
- ❖ The NF-UBC Nereus program is an international, interdisciplinary, research network designed to analyze the global ocean and improve predictions, linking science - policy - people

NF-UBC Nereus Program

- ❖ The Nereus program is a long-term (2010-2019, US\$13M) cooperation between The Nippon Foundation and The Univ. of British Columbia, conducted in partnership with Princeton, Duke, Stockholm universities, and UNEPs World Conservation Monitoring Centre / University of Cambridge
- ❖ Working across disciplines to predict the future of the global ocean and evaluate how we can develop policies that offer resilience against climate change and exploitation
- ❖ Capacity building is key – 30 fellows to be involved

Nereus?

- ❖ The original god of the sea
- ❖ Son of Pontius, the Sea and Gaia, the Earth
- ❖ The old gentleman of the sea
- ❖ Protector of fishermen –
- ❖ and he could predict the future!

NEREUS
PREDICTING THE FUTURE OCEAN

The Nereus model(ing complex): integrates many models and data

Policy & awareness

Economy & social

Seafood production

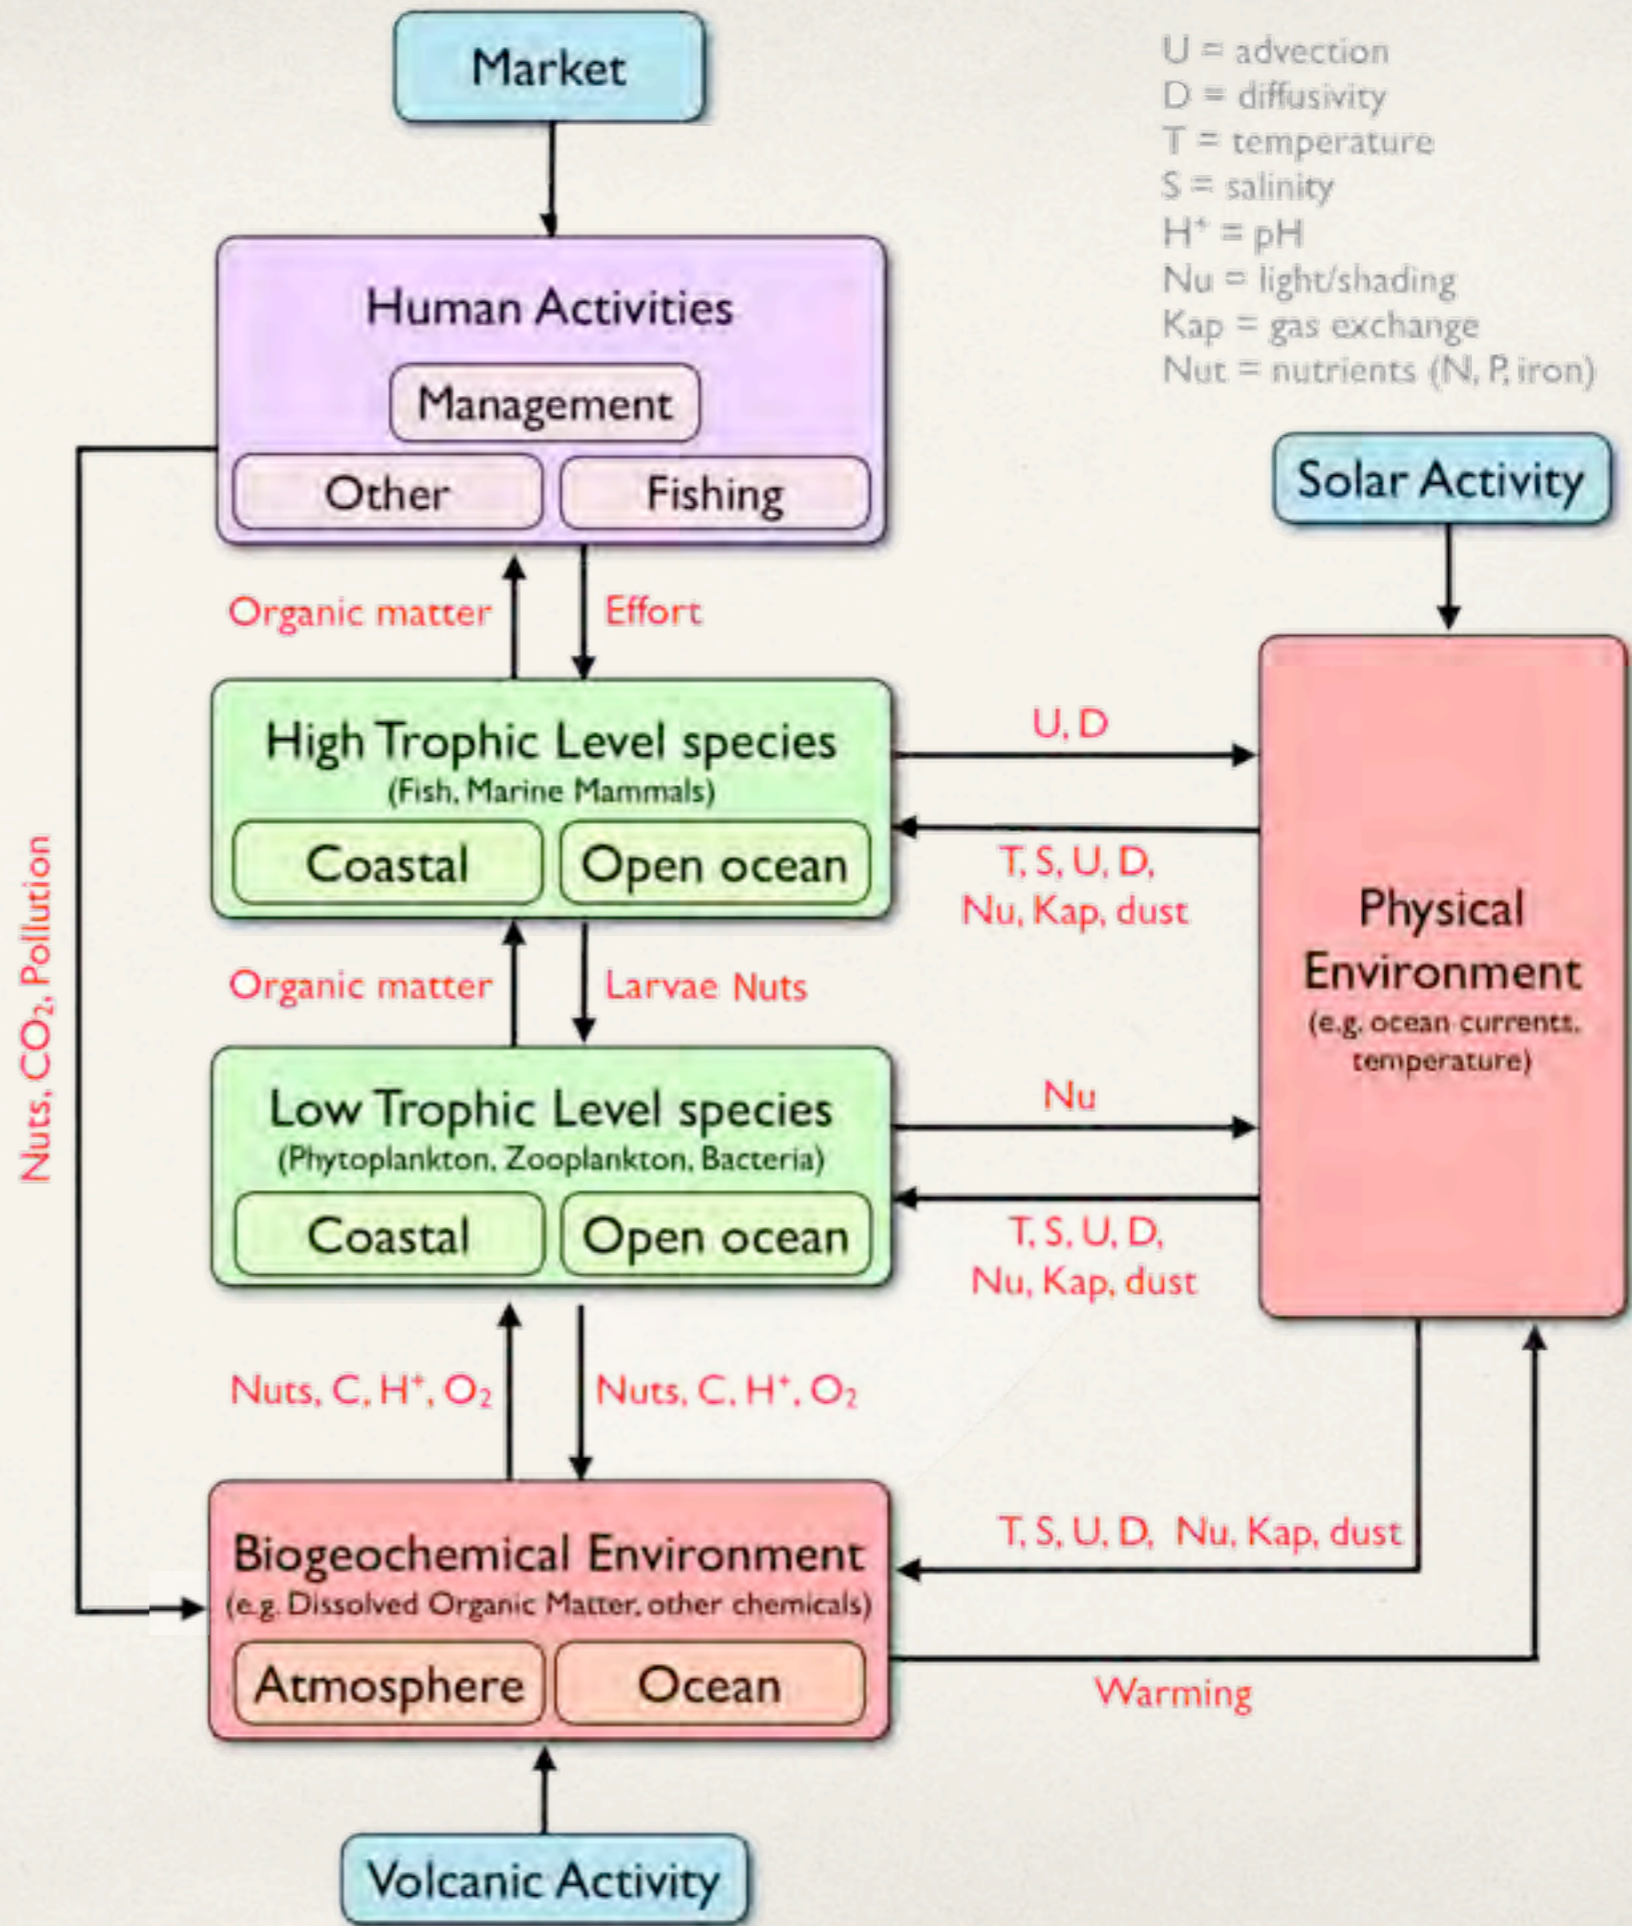

Biodiversity

Productivity

Climate & currents

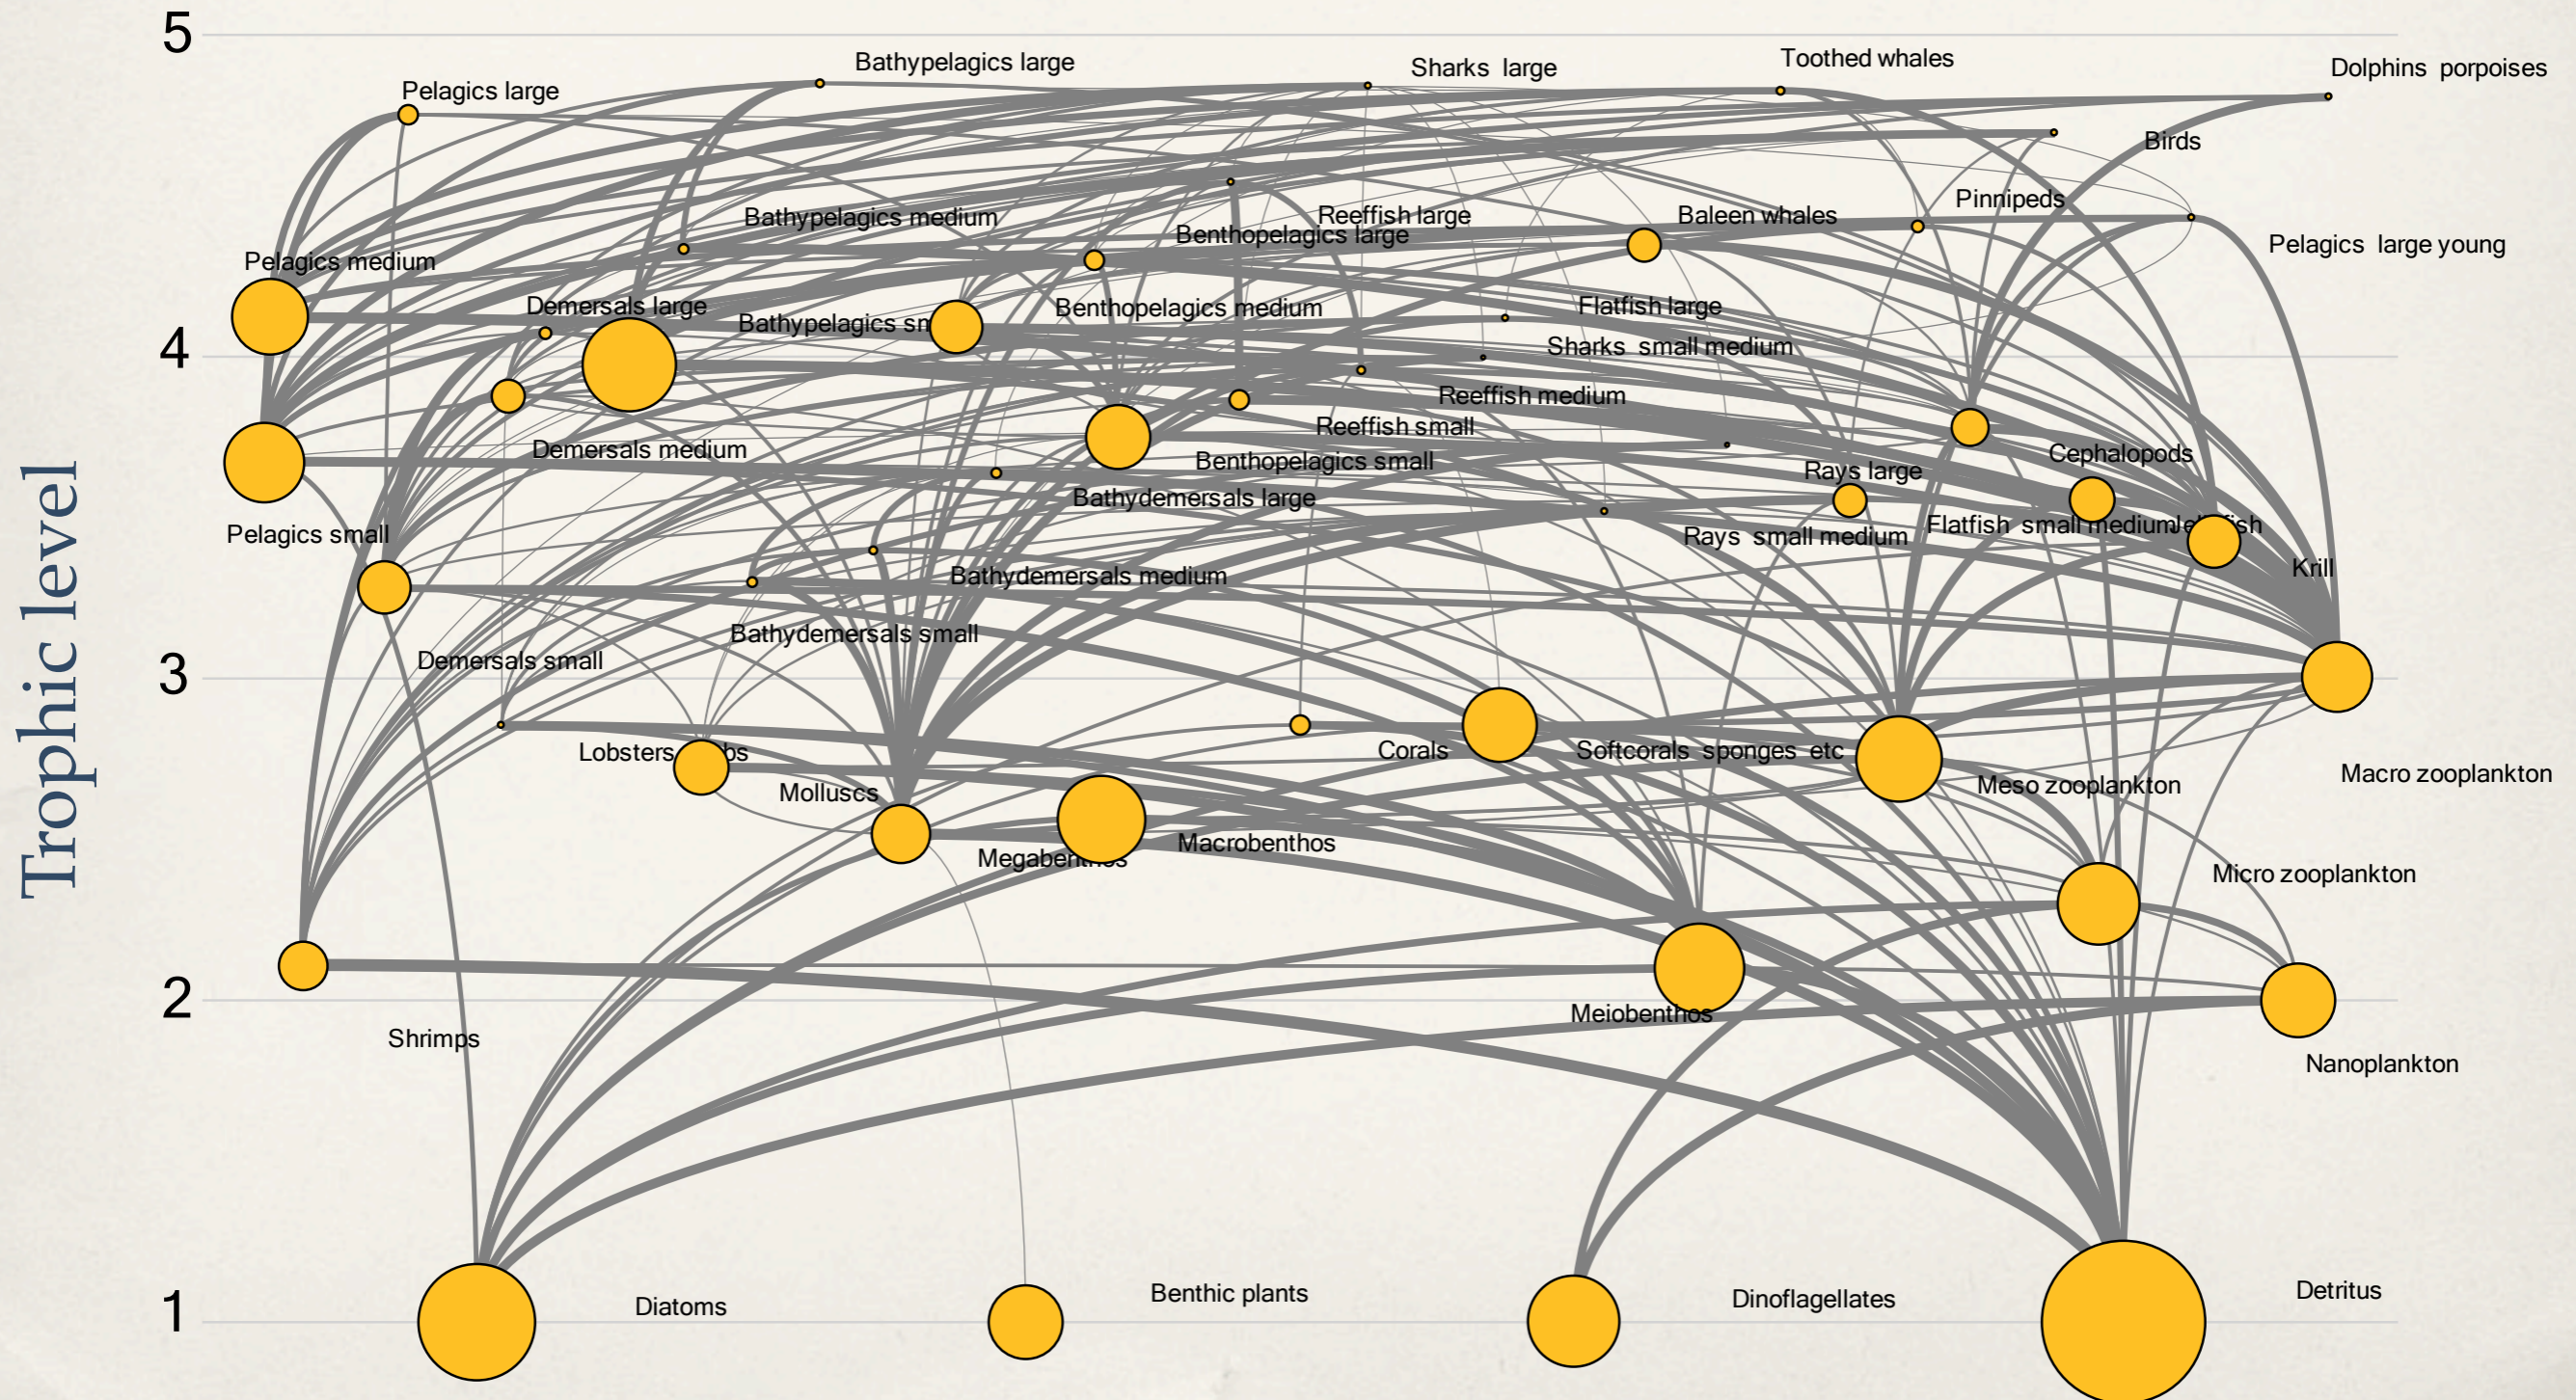

The Nereus model(ing complex)

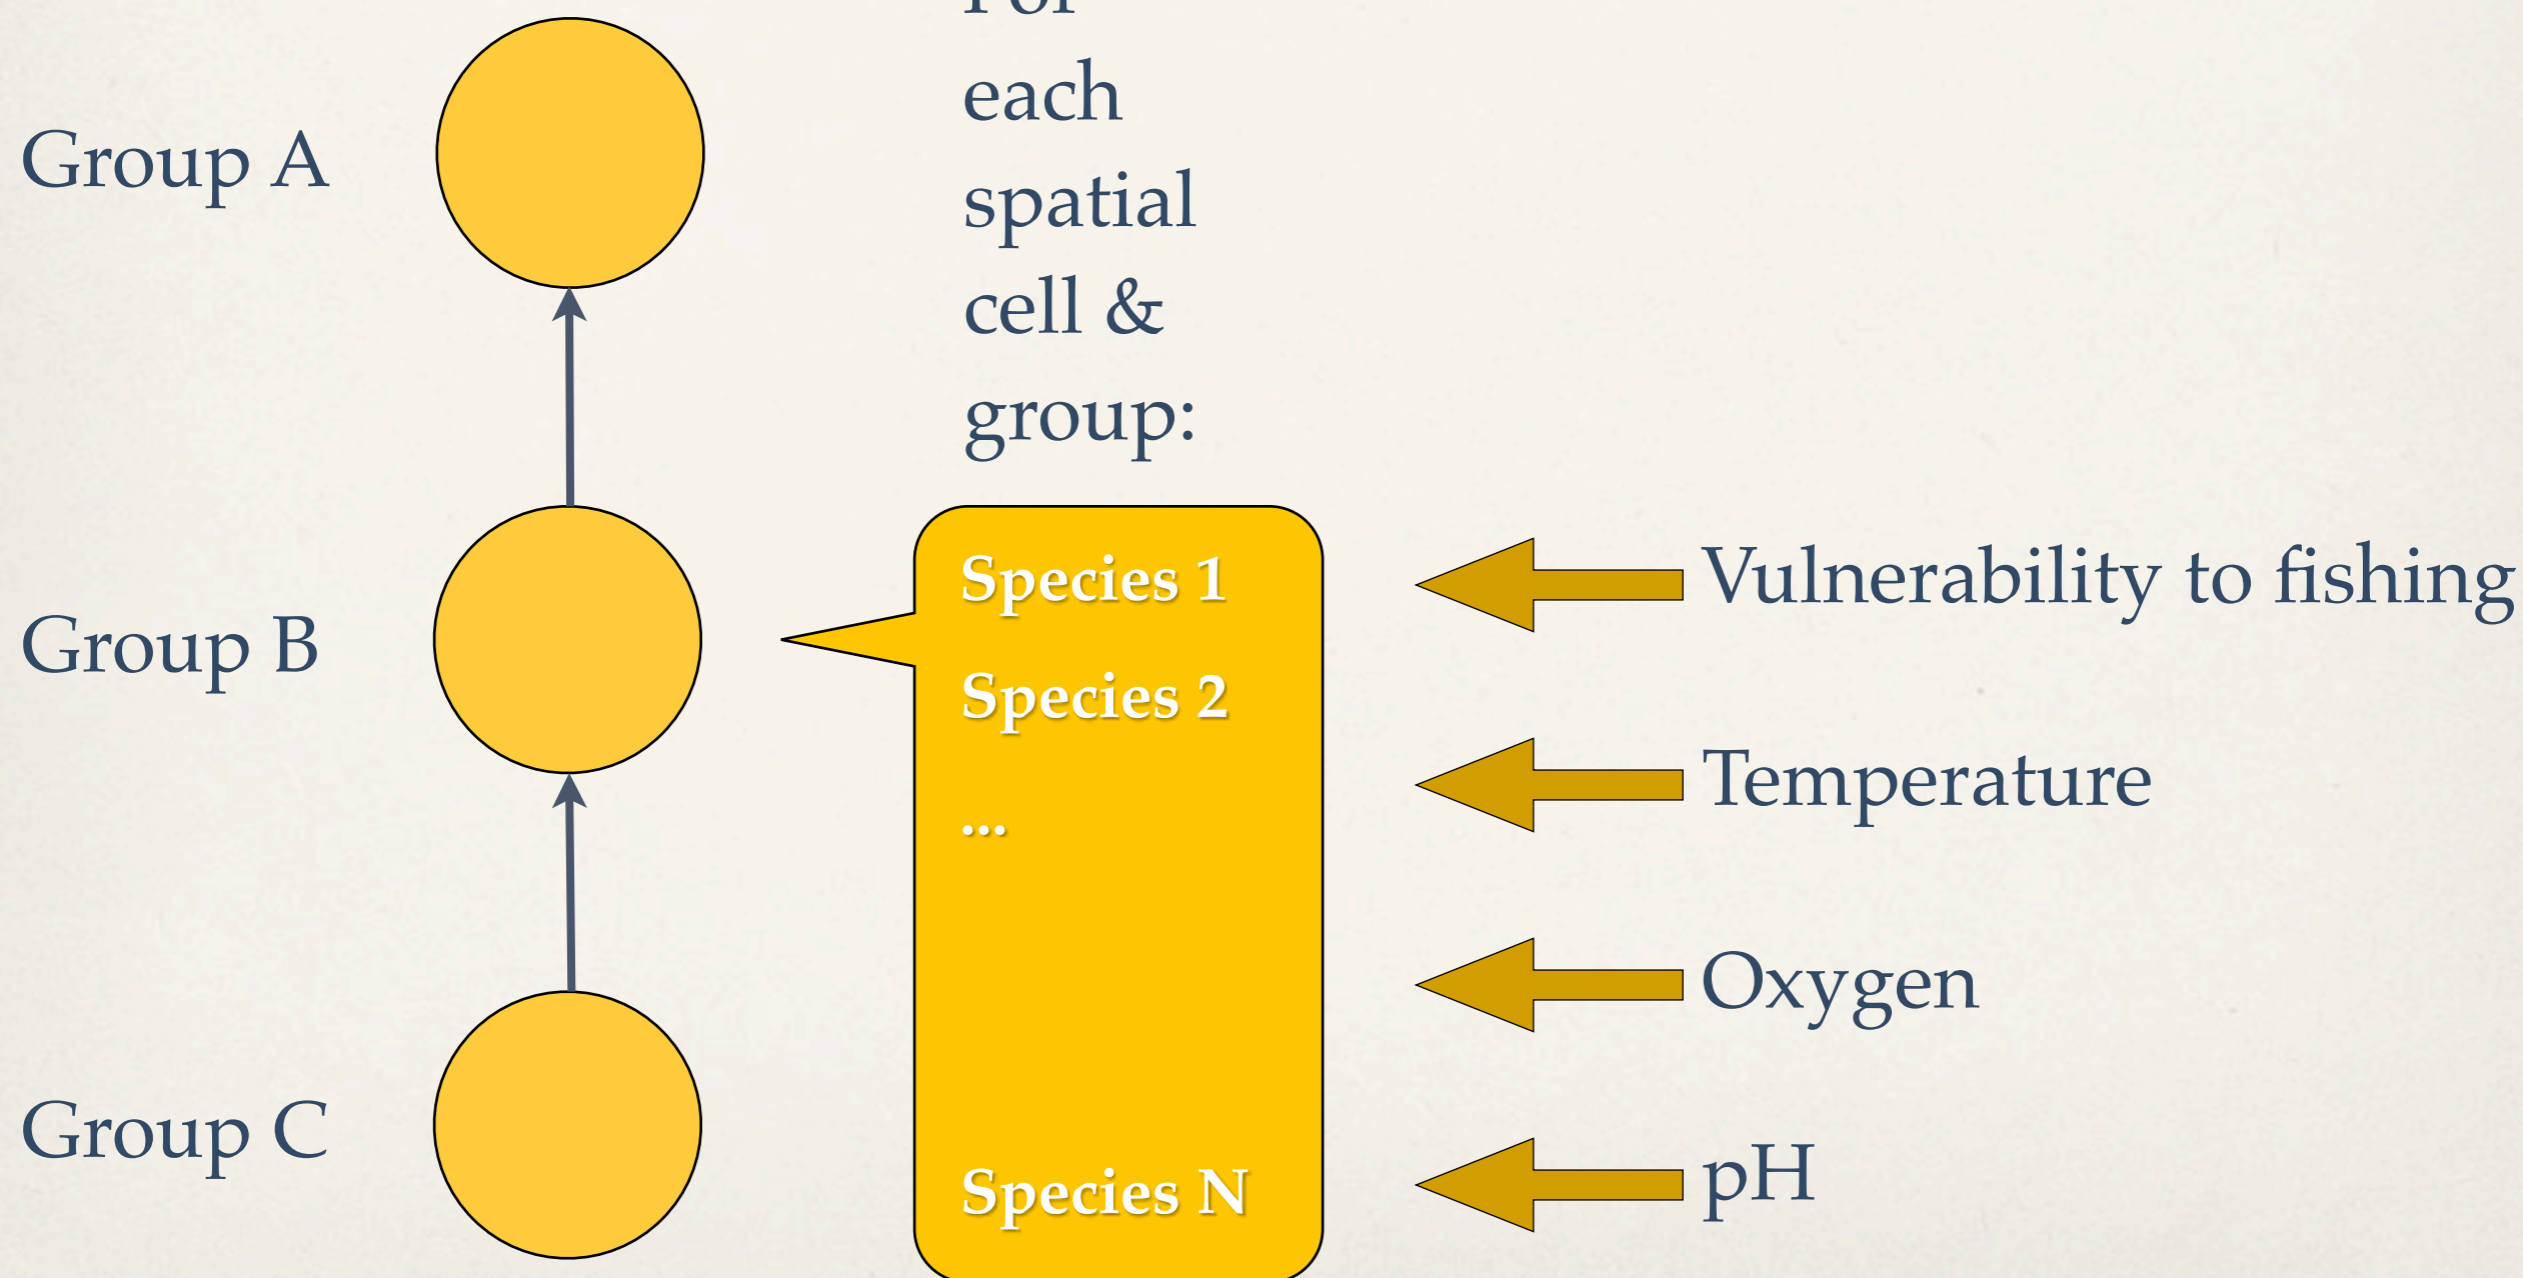

NEREUS
PREDICTING THE FUTURE OCEAN

Upper trophic levels: food web & size distribution

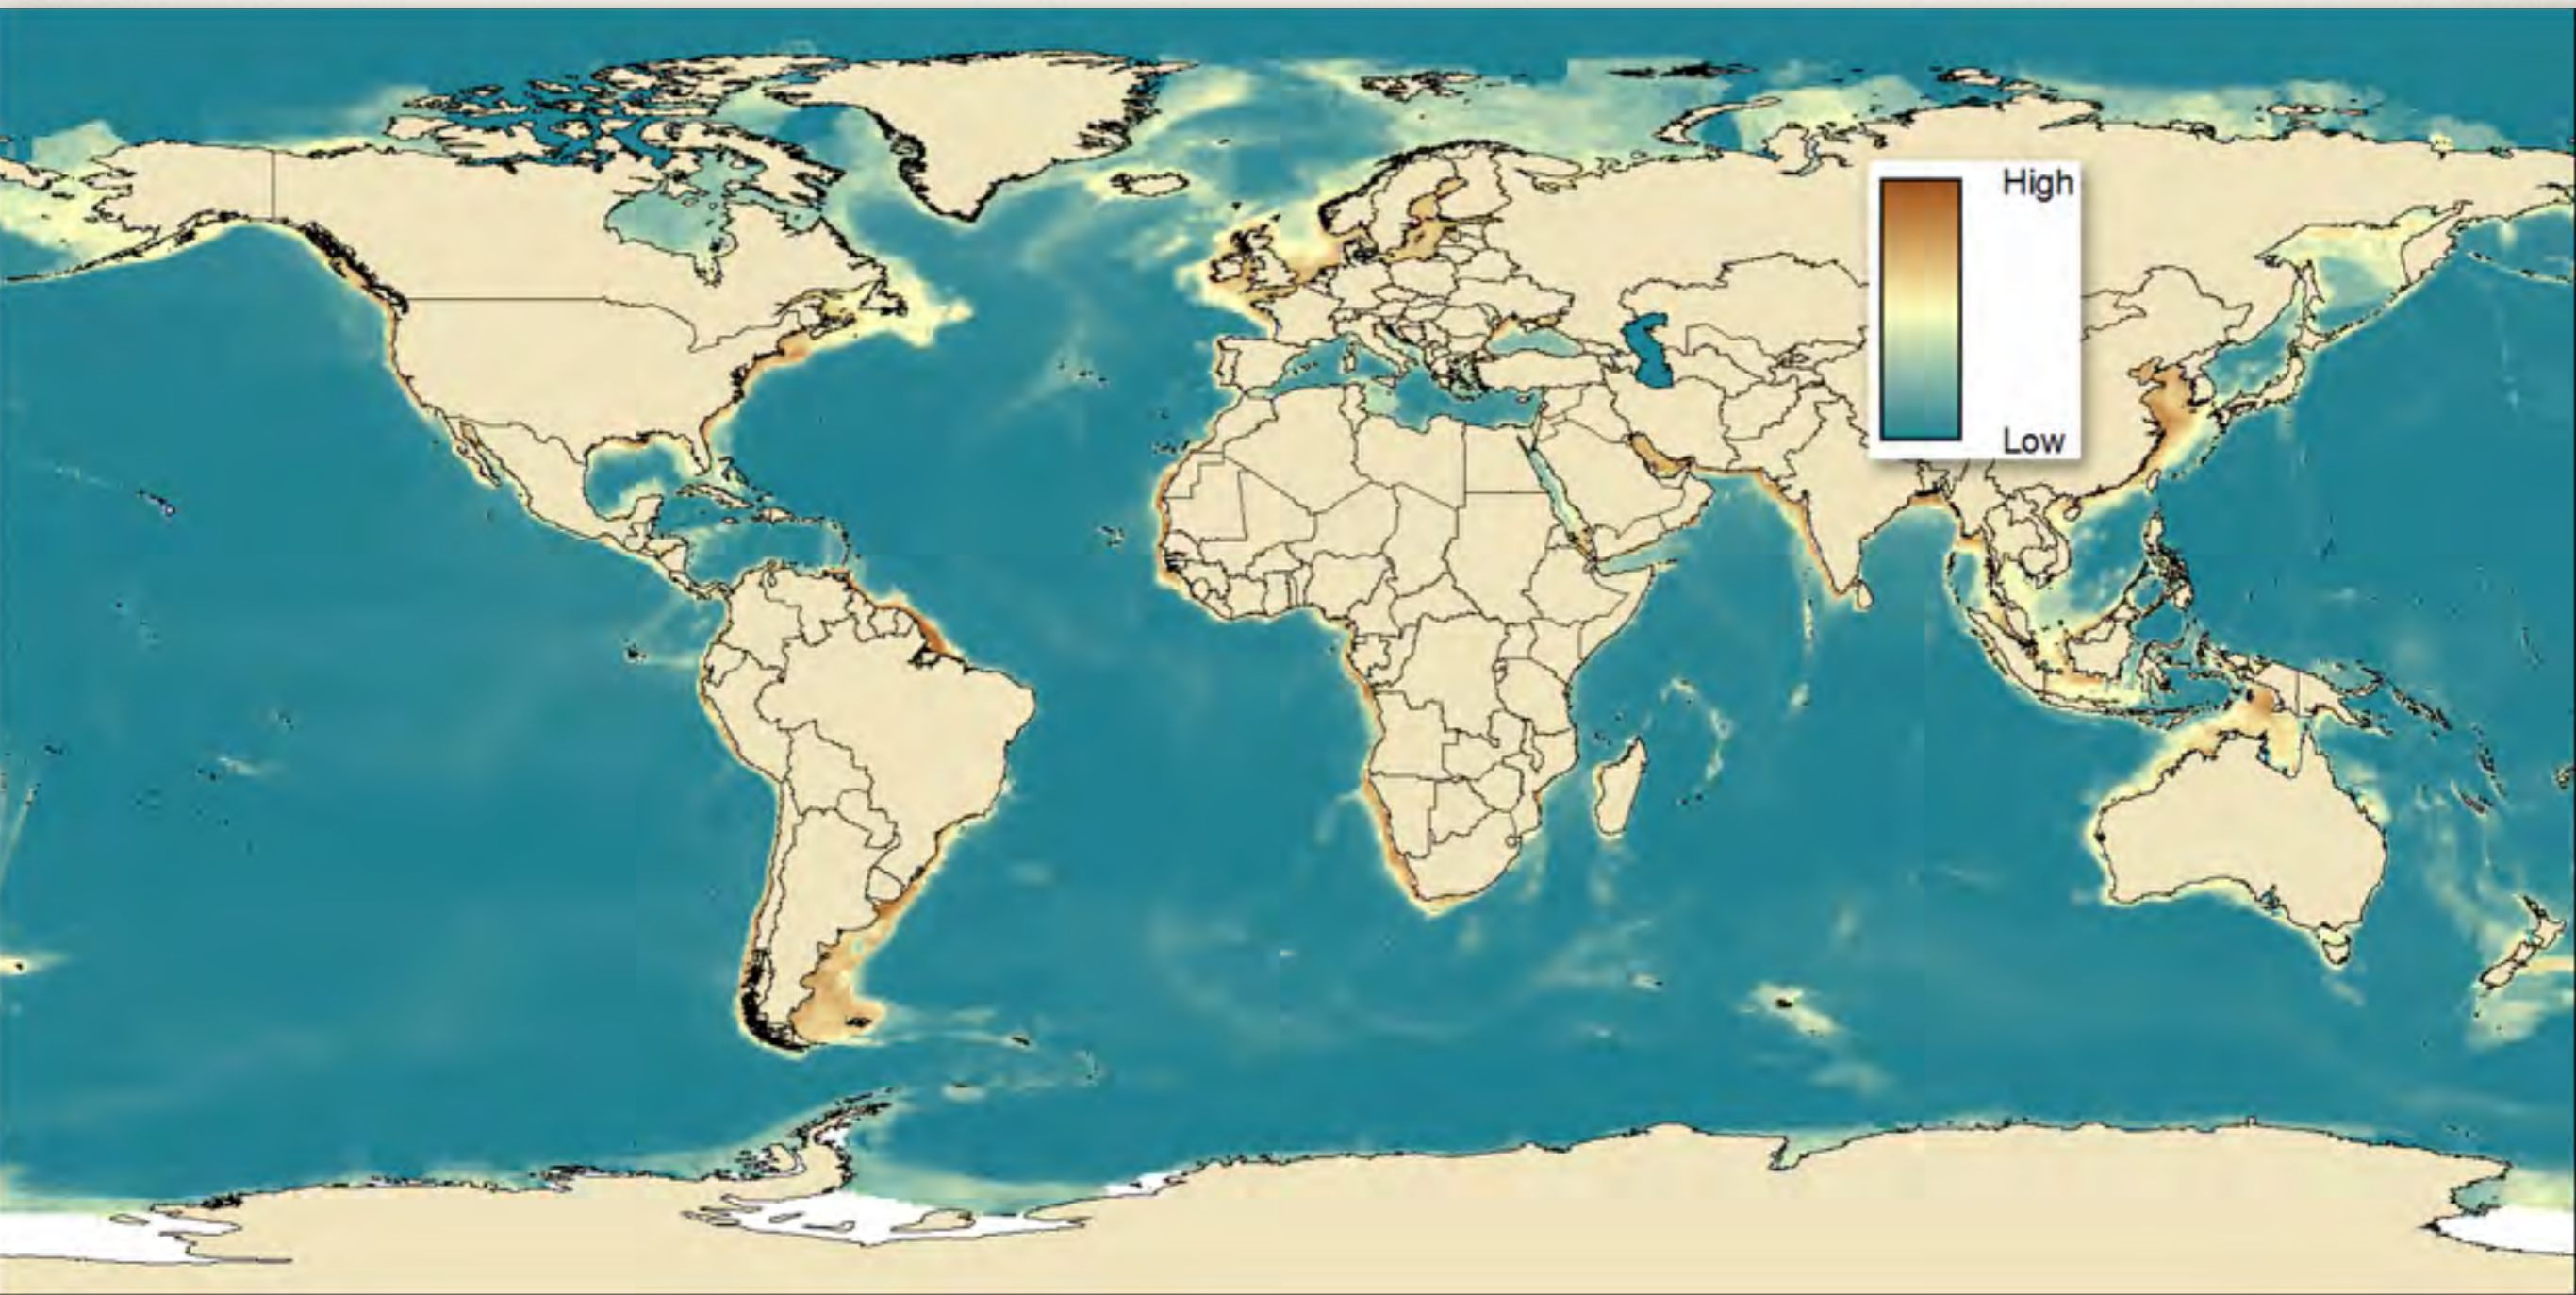

In the box: biodiversity

Early results

- ❖ The first version of the Nereus model is operative
 - ❖ The first food web model of the world ocean
- ❖ Examples of early results
 - ❖ Based on 245 fishing fleets
 - ❖ Incorporates ~1000 species
- ❖ Major additions to come as the Nereus program develops

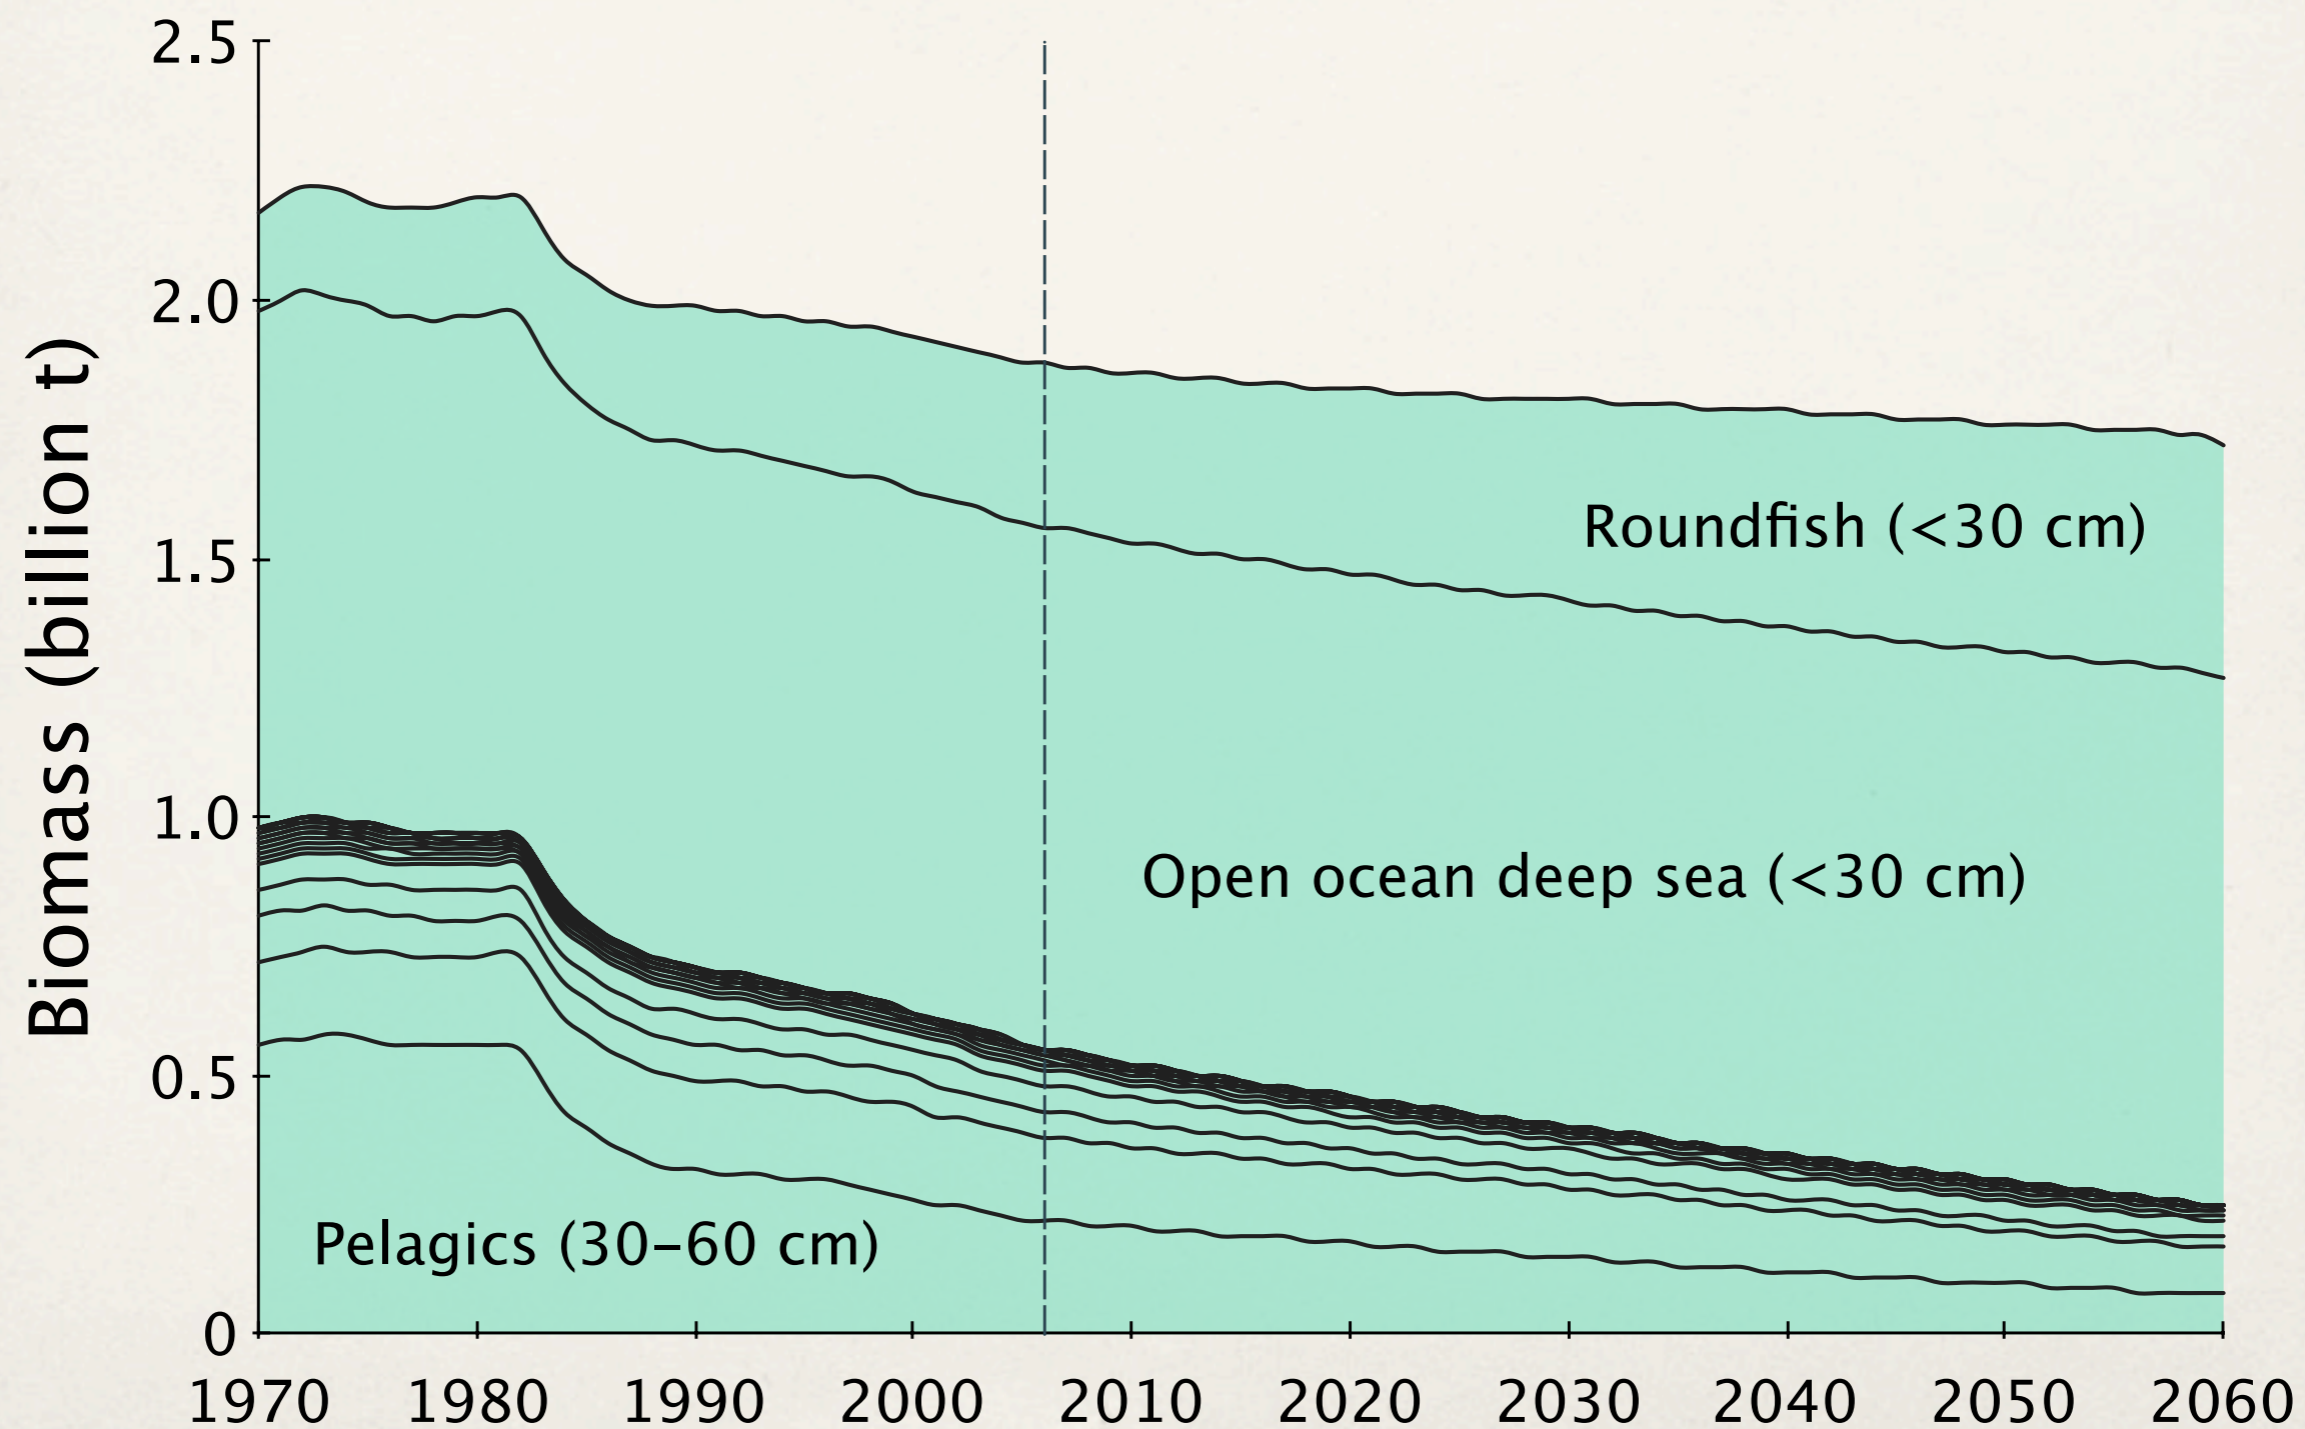

Fish biomass distribution: spatial model 252,000 cells

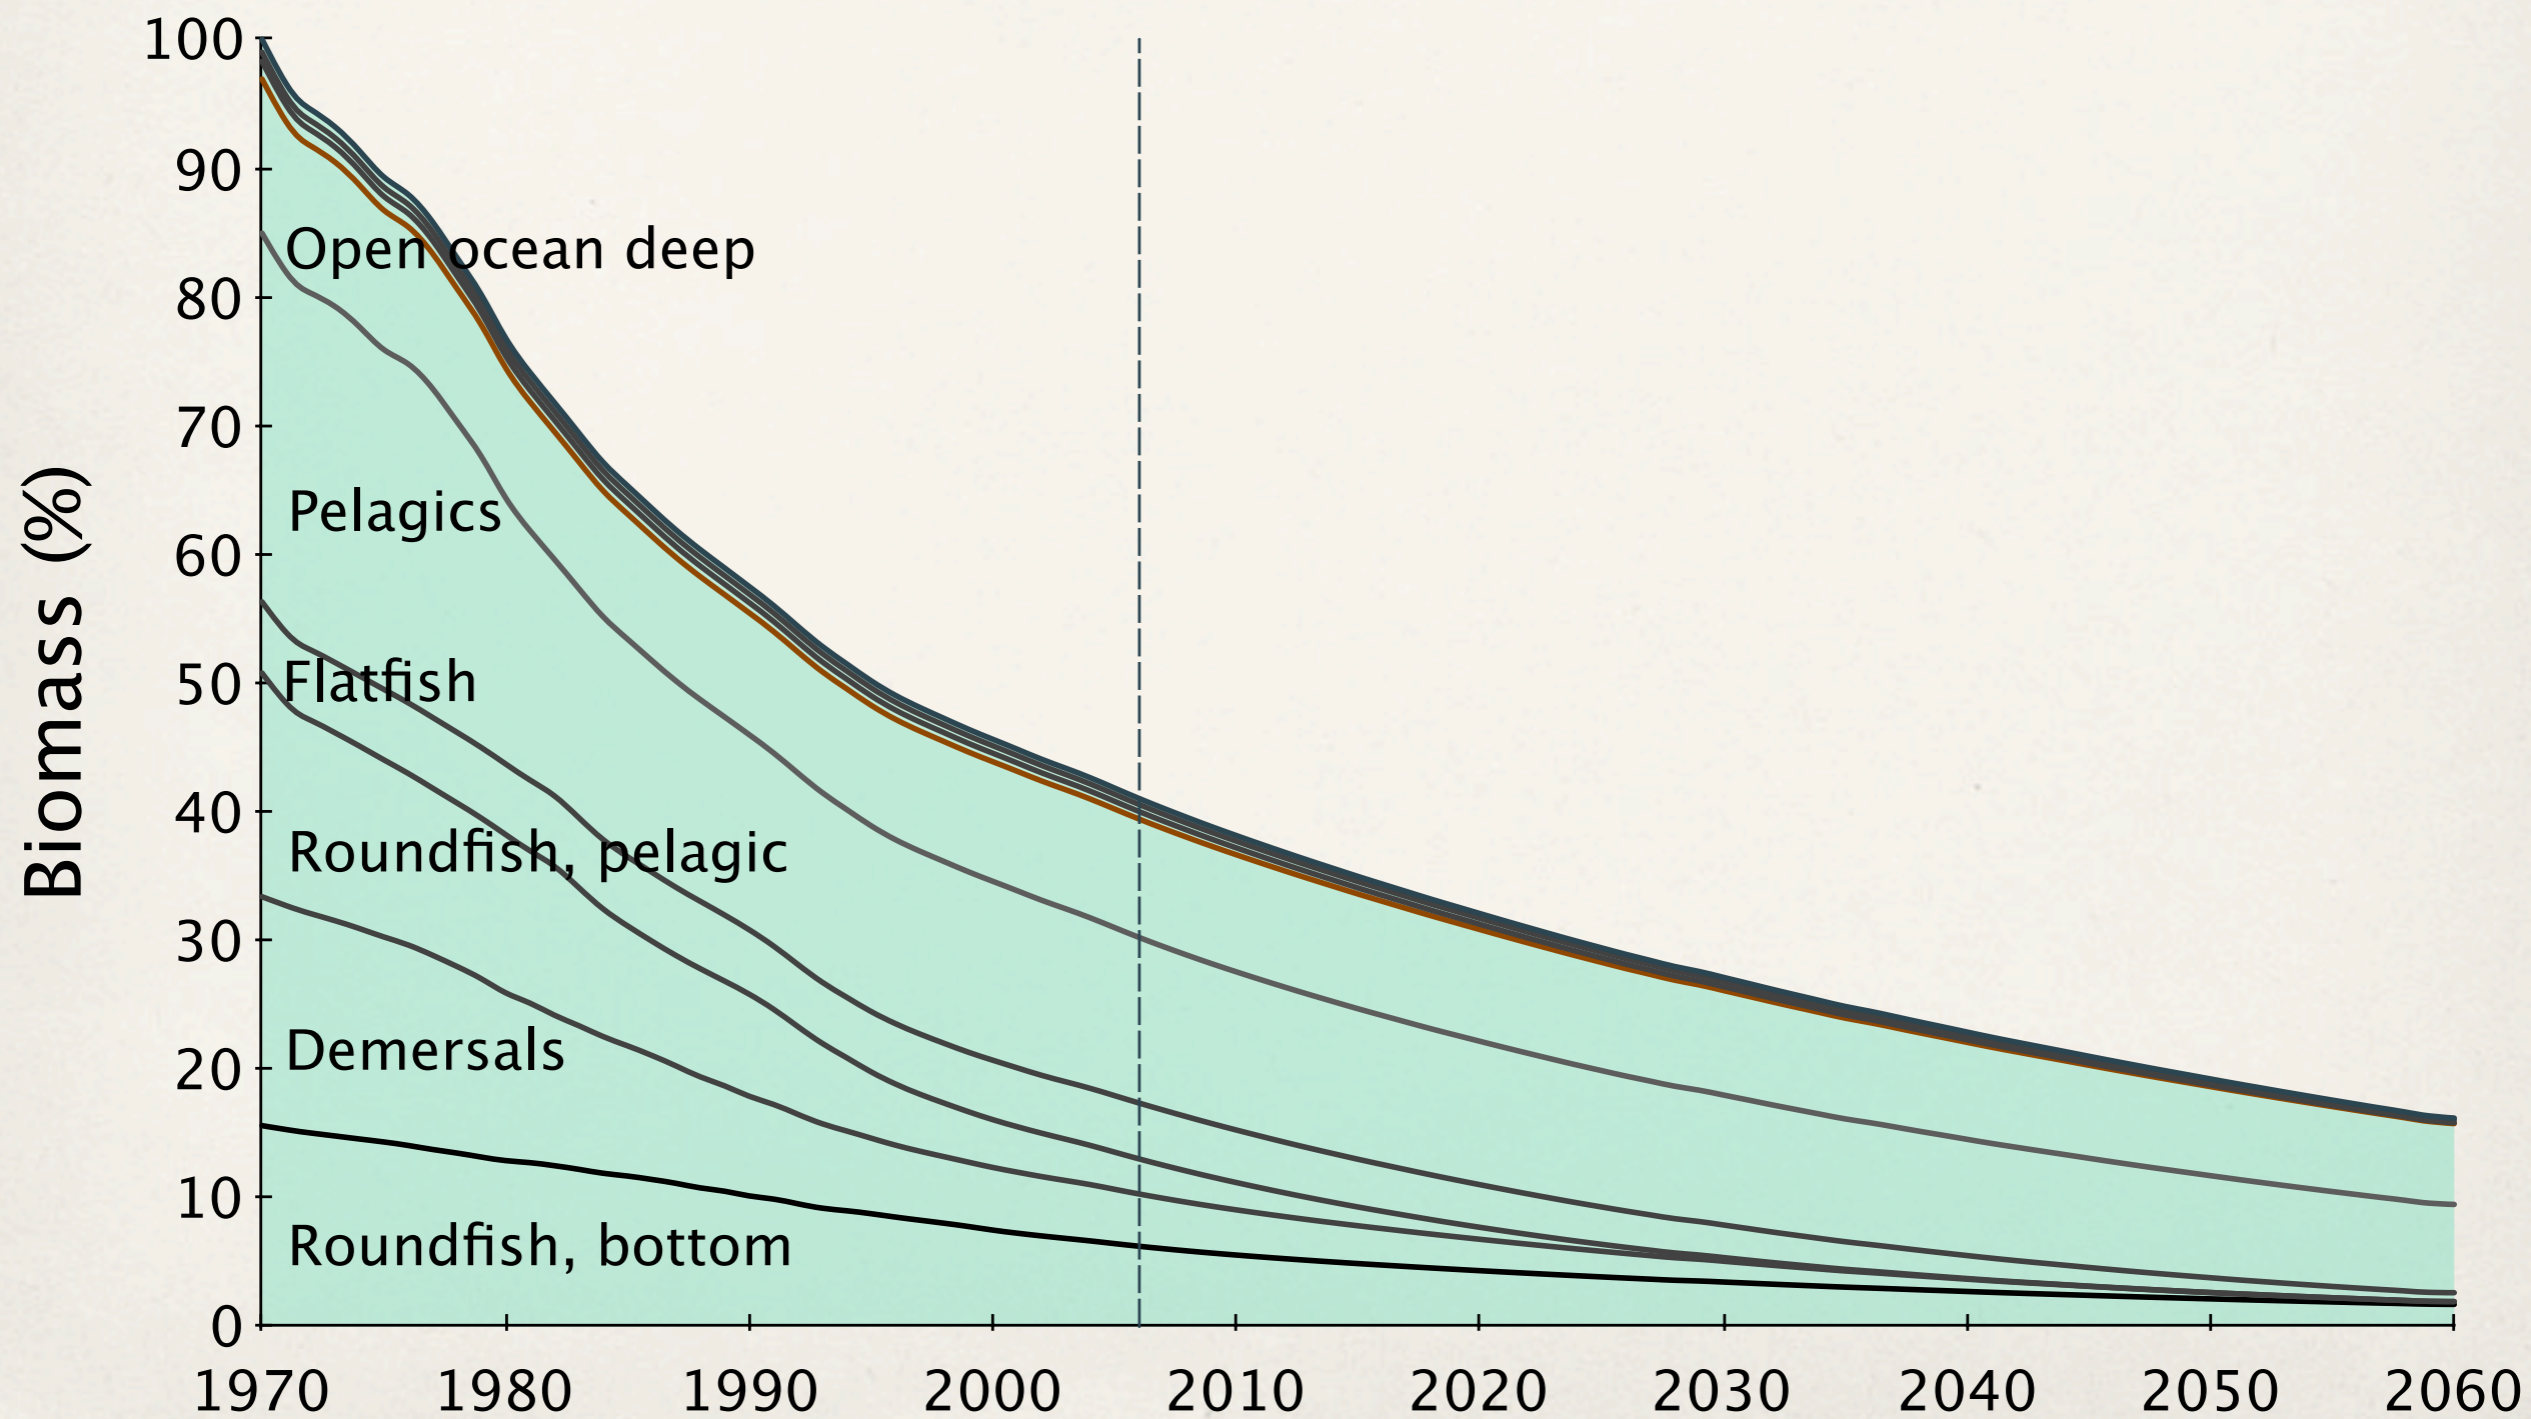

How much fish in the ocean?

- ❖ Only two previous attempts at estimating this, both much less comprehensive
- ❖ Total fish biomass ~2 billion t, >300 kg / person on earth
- ❖ Total biomass has decreased only little in the last 40 years.

Total fish biomass

Large fish biomass

Adding life to the carbon cycle

- ❖ IPCC has focused on the physical environment – up to now
- ❖ Increasing effort on evaluating impact on life in the ocean (such as this conference is an expression of)
- ❖ Impact of ocean life on the carbon cycle?
 - ❖ “Higher levels of the food chain such as fish are not of importance in controlling the surface chemical composition in most regions of the ocean”

The carbon cycle: marine biota

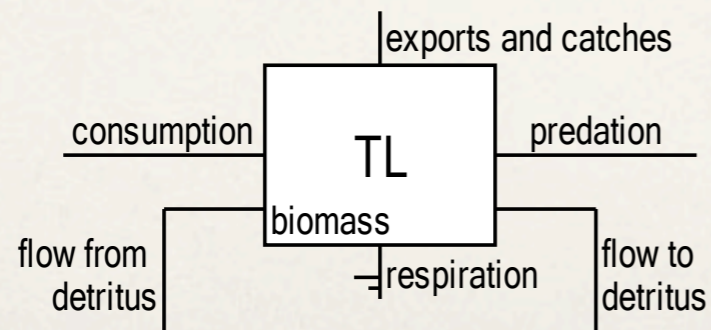

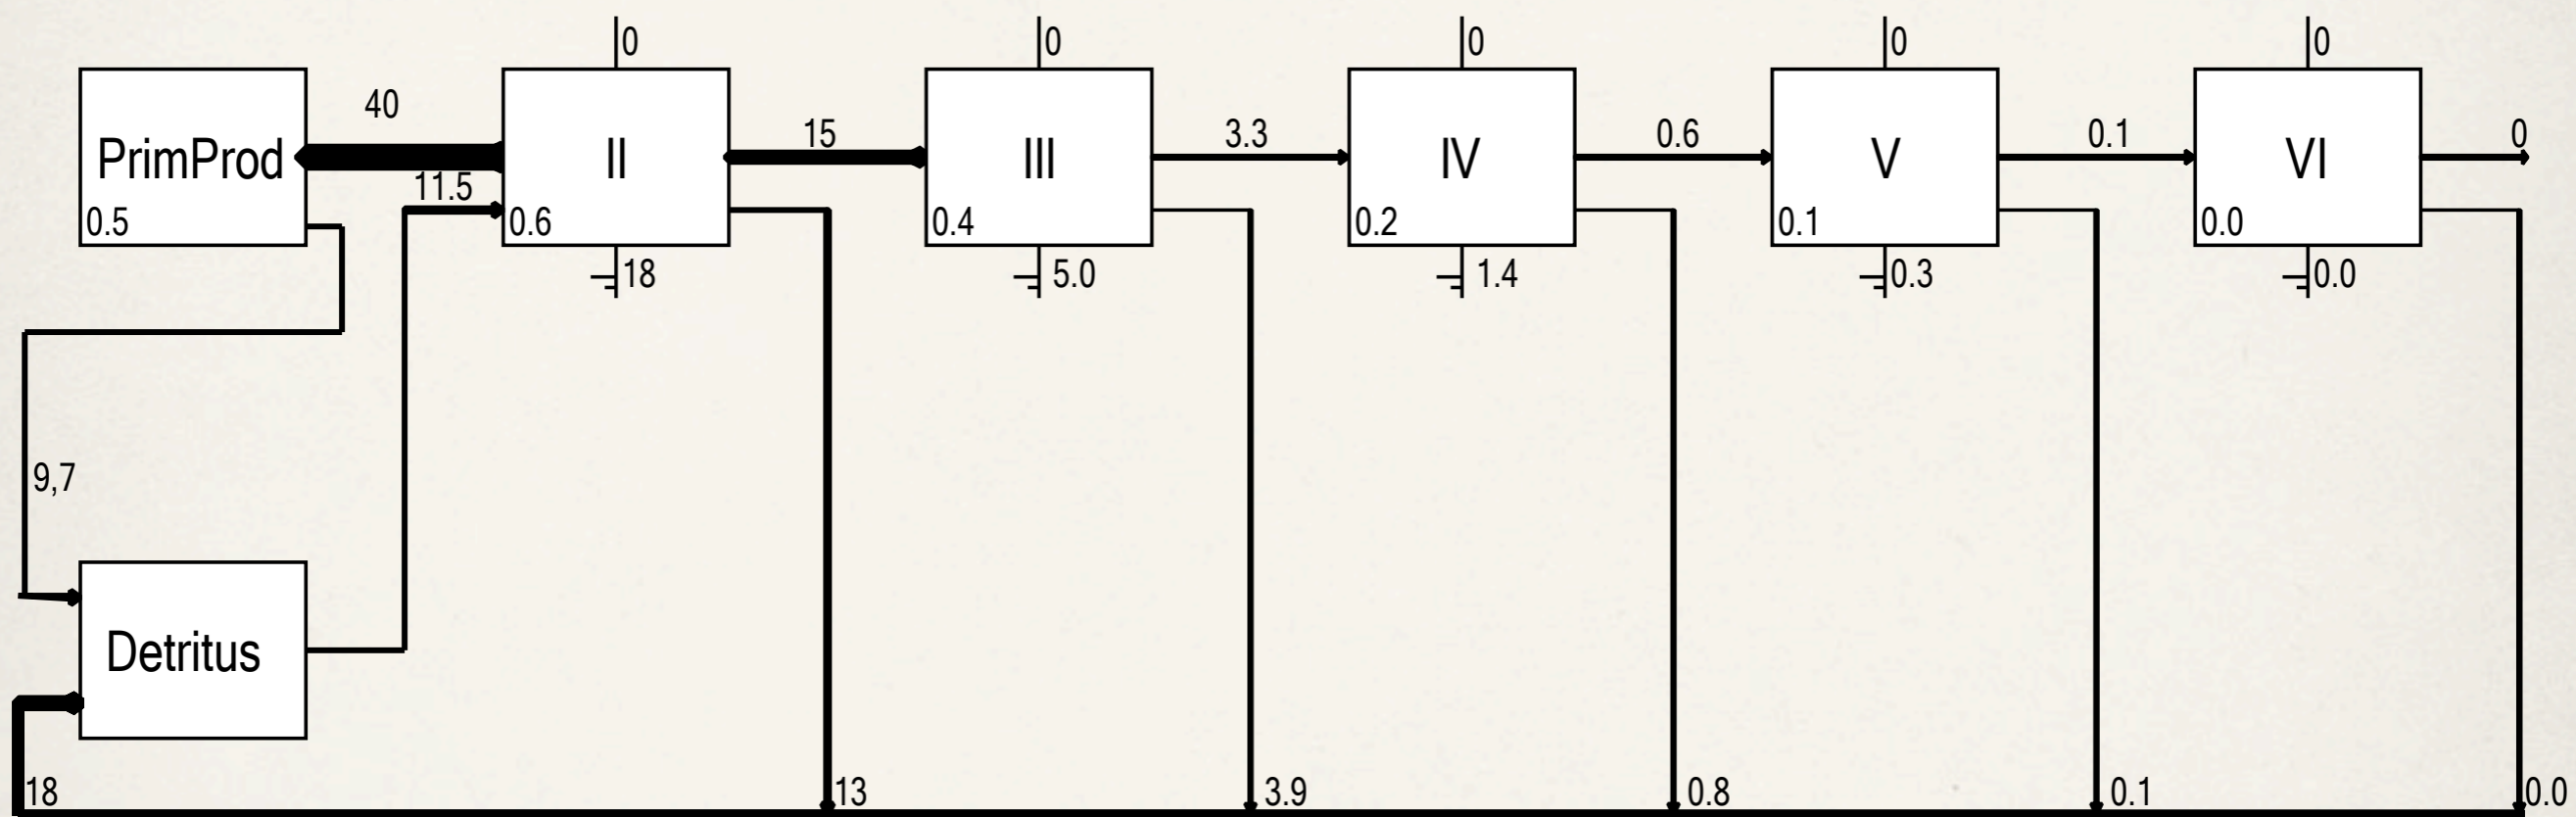

The marine biota act as a carbon pump ... provides a deep source of inorganic carbon and creates a deficit of about 10% of ΣCO_2 in surface waters ... The size of the export fluxes is not well known.

Nereus model is designed to describe interactions, but

- ❖ Flow to deep layers?
 - ❖ Not (currently) built to answer that
- ❖ Impact of nutrient recycling by biota
 - ❖ Not currently included (but neat project)

Global pools and fluxes: Nereus

Totals:

Biomasses: 2.0 PgC

Consumption: 85 PgC/yr

Ocean biota: Global pools

Suspension feeder excretion

- * Sinking rates are a.o. size-dependent
- * All small pellets (like those produced by zooplankton $> 200 \mu\text{m}$) are likely to remain within stratified photic zones, unless in aggregates

Macrozooplankton excretion

- * Froneman et al. (2002) evaluated predation impact of carnivorous macrozooplankton in the Southern Ocean during austral autumn, and found that macrozooplankton may contribute a downward flux of carbon equivalent to 0.3-9% of the total mesozooplankton stock per day
- * Assuming that this rate is representative for half the year (or half the global mesozooplankton biomass of $\sim 0.14 \text{ PgC}$):
 - * Flow to deep ocean: 1.2 PgC/yr (range 0.08–2.35)

Mesopelagic fish: live fast die young

- ❖ Global biomass: 0.16 PgC
- ❖ Consumption: >1 PgC/yr
- ❖ Excretion 16% of consumption
- ❖ 75% of excretion to deep layer
- ❖ Global sequestration of 0.05-0.22 PgC/yr

Communicating the science

- ❖ We seek policies that are resilient to climate change impacts and secures future food protection
- ❖ Public support is important for changing how we manage the oceans
- ❖

Nereus will contribute to global assessments

- ❖ We need capacity for predicting climate change impact on life in the ocean
- ❖ We fisheries scientists have been saying for forty years: cut fishing effort and all will be fine
 - ❖ But that is easier said than done
- ❖ We need to develop policies that can actually be implemented
- ❖ Calls for interdisciplinary work – for which Nereus is a poster child

Nereus will evaluate and visualize alternative future scenarios

- ❖ Should the World Trade Organization ban subsidies? Which?
- ❖ Should the UN limit FAD-tuna fishing? Shark finning?
- ❖ At UNDP: will there be alternative livelihood for fishers in coastal, tropical areas?
- ❖ At UNEP: how will the scenarios impact the ocean environment
- ❖ What types of aquaculture should be developed?
- ❖ How much of the world ocean should be protected?
- ❖ Are there policies that are resilient to change?
- ❖ ...
