Management Pressure & Confusion

Struggling snapper taken off the table

Fisherman snap at looming bans

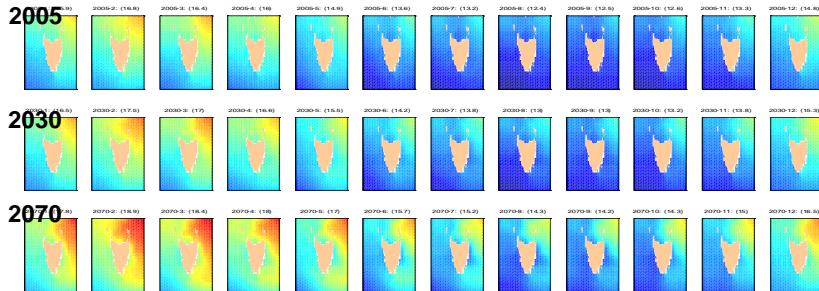

- Climate impacts on fisheries management already exist (all fisheries likely affected in some form)
- Trying to create robust climate rules (initial vulnerability assessments and projections with 5 year review)

Projected changes

- Model based projections
- Future drivers = physical change (RCP), extreme events and change in sectors (fishing, aquaculture, other sectors)

Data: CSIRO Mk 3.5 in OzClim

Sources of Uncertainty

- Parameters (e.g. growth, fecundity)
- Response curves (what effected by climate & how)
- Structural uncertainty (what should be in the model & how connected)
- Used multiple models & variants

Kirtman et al 2013

- Long term (2050) critical components will be evolution, acclimation & **human responses** (if threshold passed, step changes needed)

Models

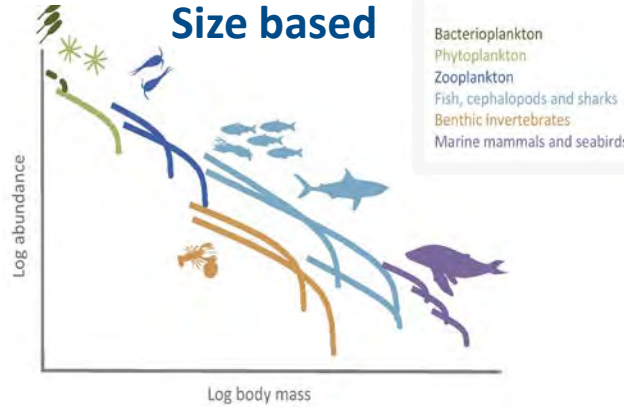

FISHERIES & MARINE ECOSYSTEM

MODEL INTERCOMPARISON PROJECT

Diversity of model approaches

Species distributions

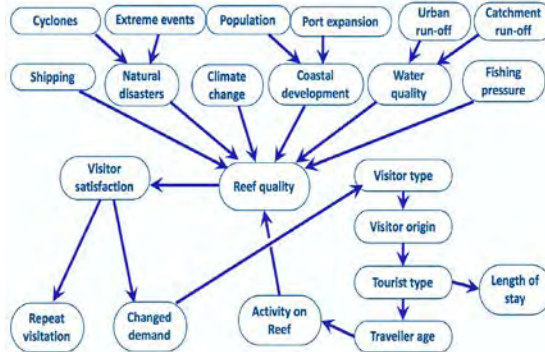

Size based

Trophic

Agent based, hybrid & end-to-end models

Bayesian networks

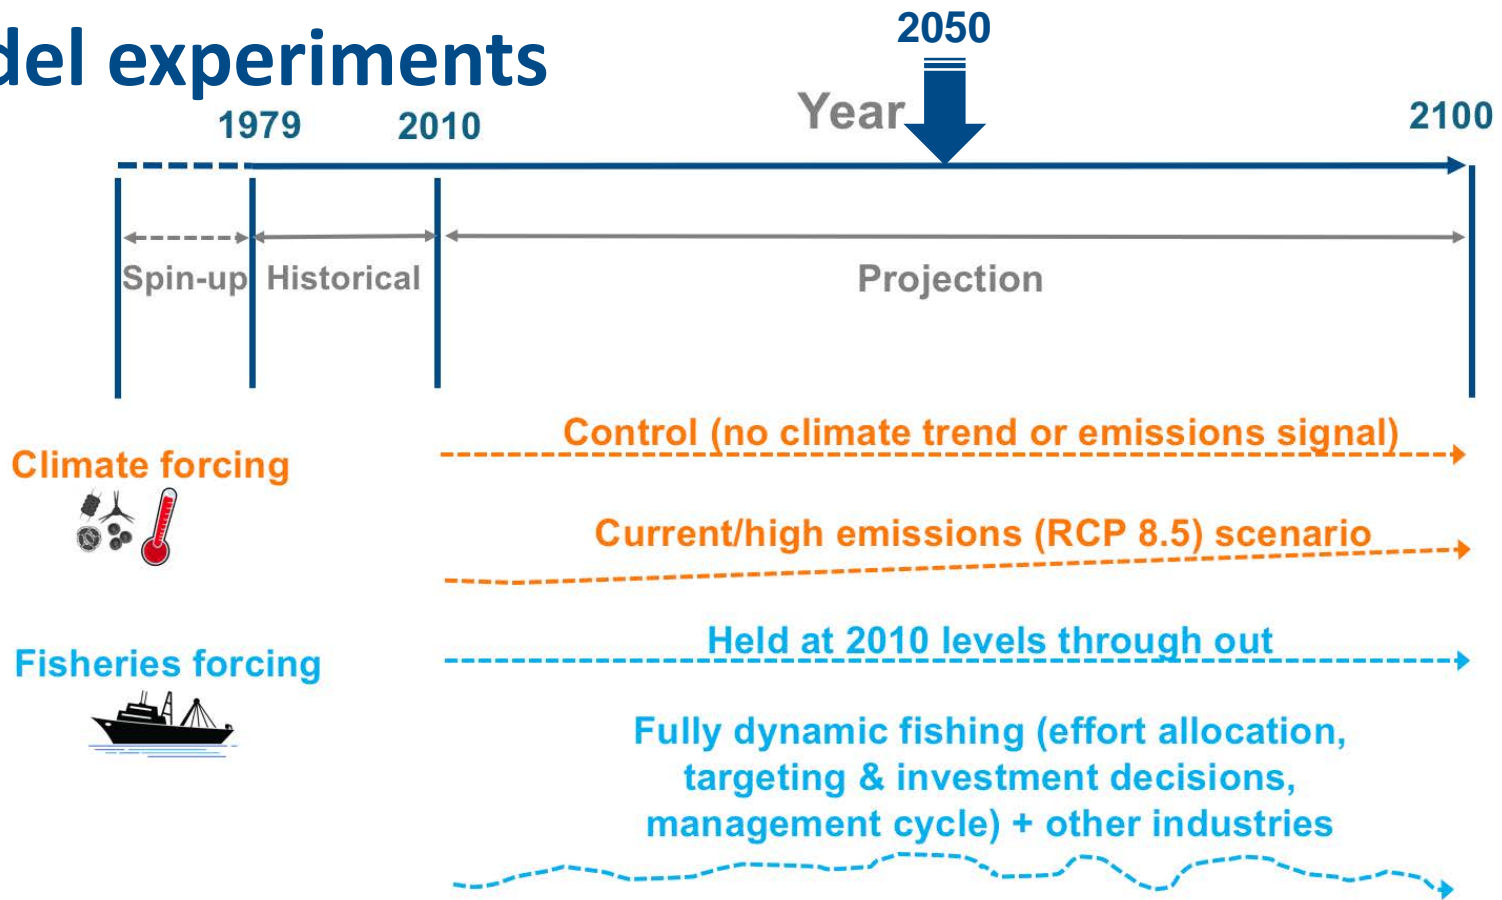

Minimum realistic (MICE)

Ecosystem Model Types Used

Property	Distribution Model	Size-based	MICE	Ecopath with Ecosim (EwE)	Atlantis
Forced by physical drivers	✓		✓		✓
Forced with primary production	✓	✓	✓	✓	
Physiological processes	✓				✓
Trophic interactions		✓		✓	✓
Size-based interactions		✓			✓
Habitat interactions	✓				✓
Constant fishing mortality			✓	✓	✓ v1
Dynamic fishing responses					✓ v2
Spatial	✓	✓			✓

Model experiments

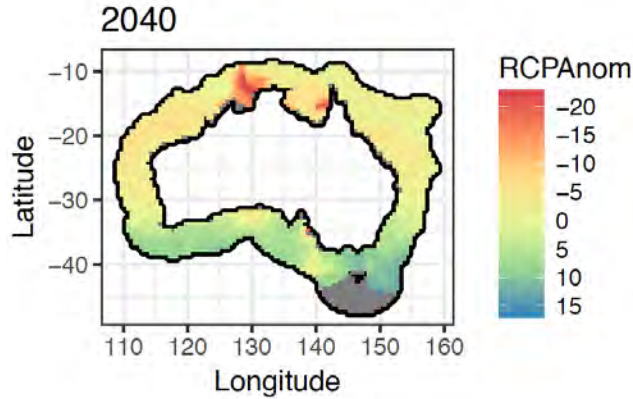

Model experiments

	Control (no climate signal)	Current/High emissions (RCP 8.5)
Constant fishing pressure (2010 Fs)	✓ ✓	✓ ✓
Dynamic fishing (& other industries)	✓	✓

Results

- Per species

- Total biomass

- Trajectories of biomass & catch (species & functional groups)

Results – Species distribution models

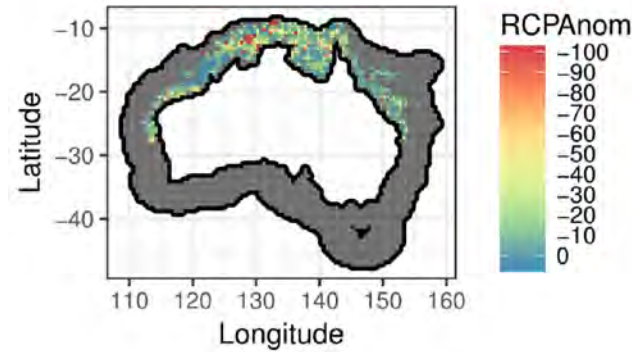

2020

- Per species (~150 species), mixed quality

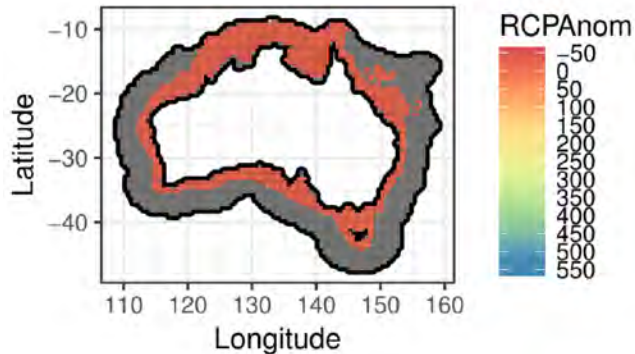

Southern Bluefin Tuna

Endeavour Prawn

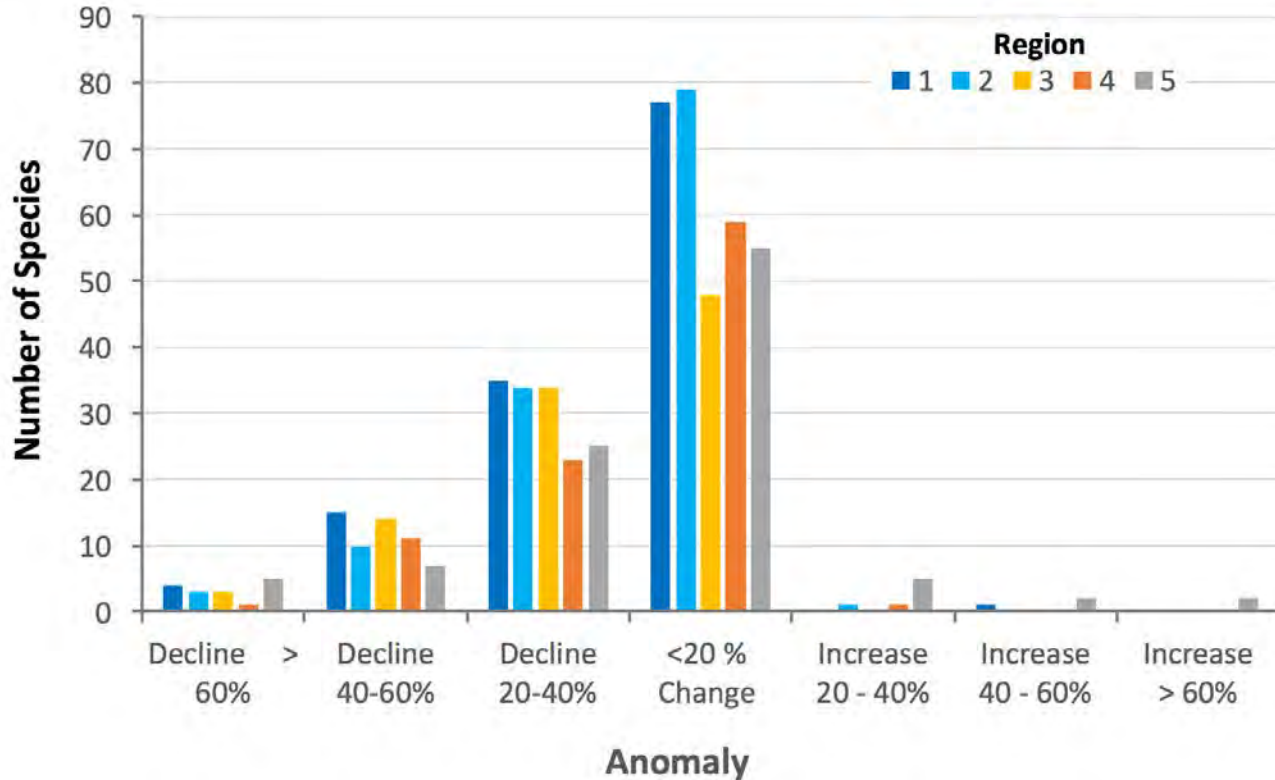

Jack Mackerel

Silver Warehou

Results – Species distribution models

- Species distribution models based on preferred niches = declines

Results – With trophic connections

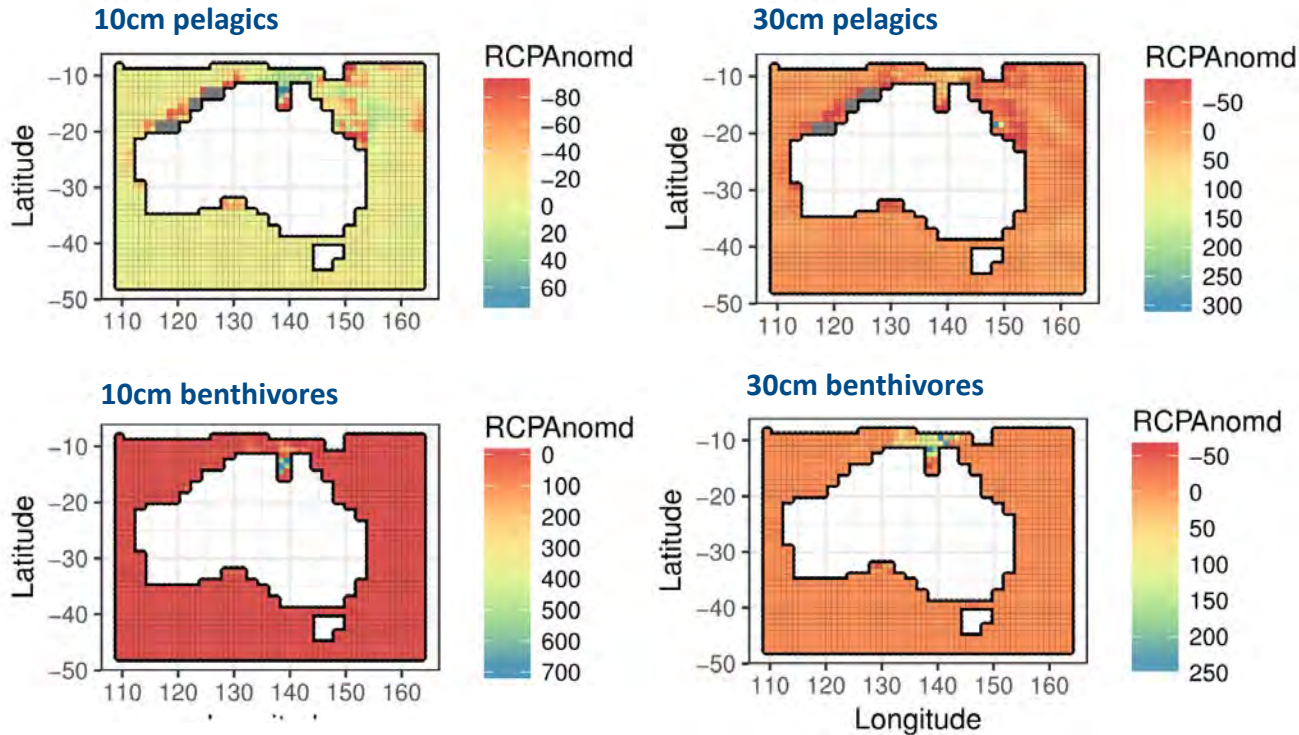

- Trophic interactions show things more complicated than shifts alone

Results - Size-based model

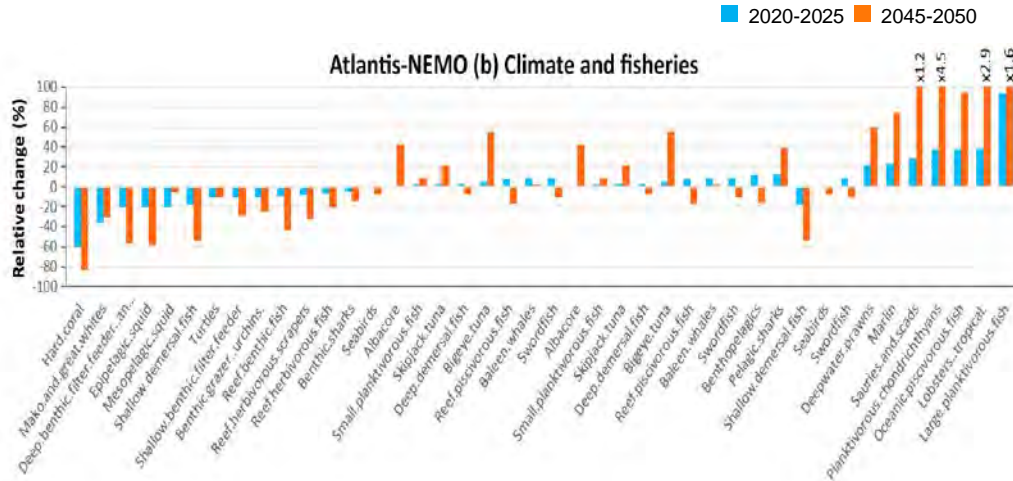

2025

- Not too much change, except in the north

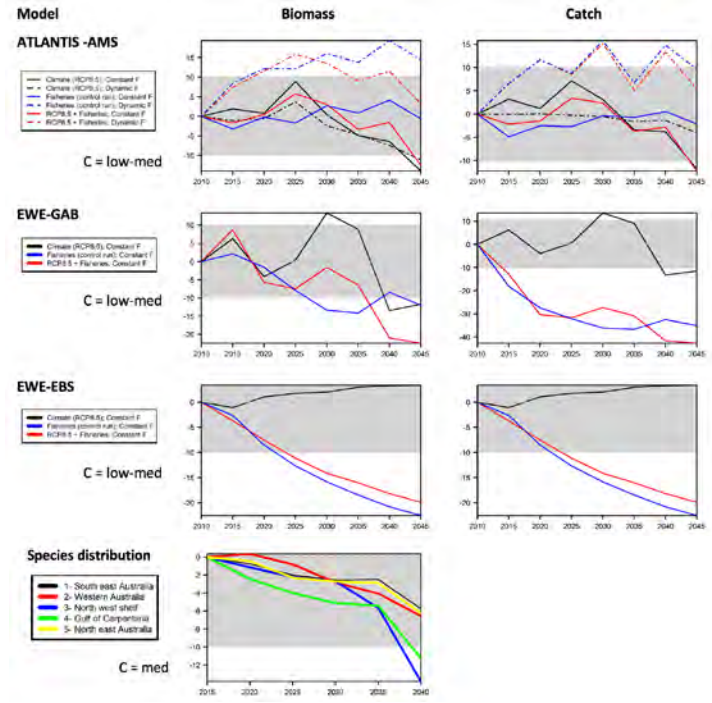

Other Results – trophic models

- Whole of system: lots of variation (some up, some down; changing through time)

- Multiple trajectories: biomass & catch (all target species, major bycatch, protected species)
- Ensemble of models (agreement & exceptions)

Synthesis of Multiple Lines of Evidence

Potential Changes in Value of Commonwealth Fisheries

Model predictions of direction of change in future fisheries value

2020-2025
2030-2035

Climate Footprint in Commonwealth Fisheries

2020-2025

Experts were asked to judge the sensitivity of the main fisheries species

Computer models were also used to explore potential futures for the main fished species & the effects on the gross value of fisheries

MODELS PREDICTING STOCK CHANGES

Level of Certainty

? Low

✓ Moderate

NPF: All potentially sensitive, but may benefit in short term

\$ Value may increase by 20% but up to 45% drop possible

TROPICAL FISHERIES: All potentially sensitive, apparently few 'winners'

\$ Value may increase by 20% but it may drop by 50%

ETBF: All potentially sensitive, but many will likely still cope

\$ Value likely to hold steady but up to 35% drop possible

SPF: All potentially sensitive, but many will likely still cope

\$ Value may increase by up to 40%

SESSF: 40% potentially sensitive to further change, but may be slow to come. Recovery from past change unlikely

\$ Small change ($\pm 10\%$) in value most likely, but a slim chance of collapse exists, if sudden regime change occurs

60% Target species have a potential sensitivity

The average may remain relatively stable, but variability will increase & species are already moving. State fisheries will likely be more heavily impacted.

2020: Likely little change, or small shifts

- Pelagic – mostly stable or increasing
- Tropical – winners & losers (lobsters in trouble)
- Temperate – mostly stable or mixed (but key species likely decreasing or failing to recover)

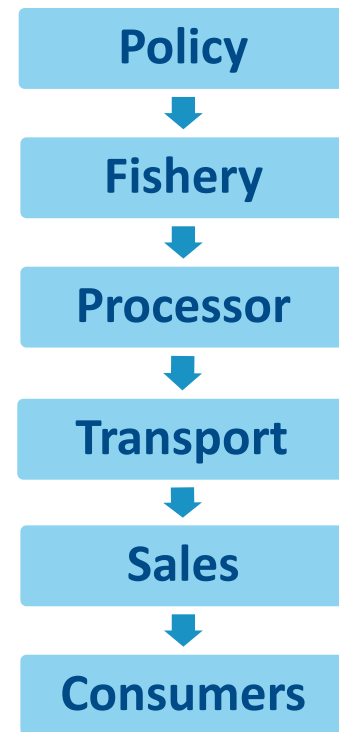

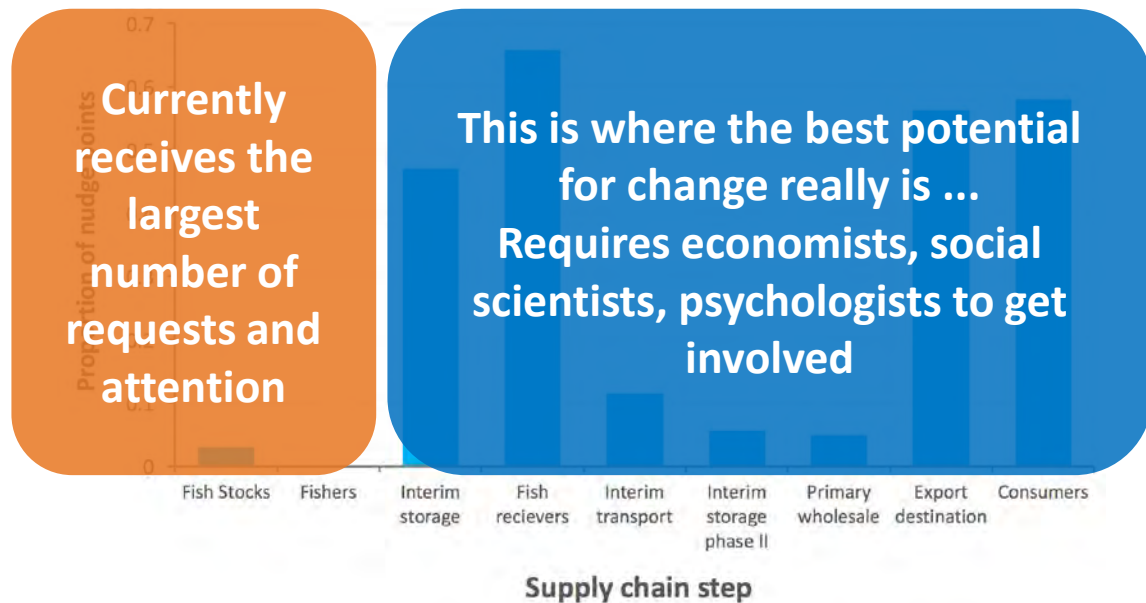

2050: Bigger changes likely... but messy

- More uncertainty (model divergence)
- **Pelagics** – begin decreasing
- **Tropical** – Lots of losers
- **Temperate** – Toss a coin... (lots of change or adaptation, models disagree about the outcomes... possible regime shift)
- **Invertebrates & shallow demersal ecosystems more sensitive**
(some species already struggling & failing to recover)
- **High variability** in space & time (& between sectors)
- There will be **winners & losers**, winners likely beyond species currently managed

Adaptation options & Barriers

- Most of the proposed options are to do with fishing (but most of these are already being done)
- Rest if the supply chain not thinking about climate yet

Recommendations

- New tools may need to be discussed (e.g. interventions; frame based management rules)
- Iterative fisheries forecasts (short & long term) will help, but need good supporting data streams
- Cross jurisdiction management coordination
- Plan how to deal with differential outcomes
- Flexible regulations & non-static assessments (and forecasts)

Summary

- Managing in climate context already
- Short term (5-10 years) of far more current interest operationally
- Don't shy away from structural uncertainty
- Core of short term = stability, but variation important & growing
- Southern change has started, beginning in the north
- Differential outcomes
- Watchwords – Flexibility & Prioritisation
