“whole-genome shotgun sequencing”

Environmental Genome Shotgun Sequencing of the Sargasso Sea

**1800 genomic species
based on sequence relatedness, including
148 previously unknown bacterial phylotypes
over 1.2 million previously unknown genes**

ABSTRACT

We have applied “whole-genome shotgun sequencing” to microbial populations collected en masse on tangential flow and impact filters from seawater samples collected from the Sargasso Sea near Bermuda. A total of 1.045 billion base pairs of nonredundant sequence was generated, annotated, and analyzed to elucidate the gene content, diversity, and relative abundance of the organisms within these environmental samples. These data are estimated to derive from at least 1800 genomic species based on sequence relatedness, including 148 previously unknown bacterial phylotypes. We have identified over 1.2 million previously unknown genes represented in these samples, including more than 782 new rhodopsin-like photoreceptors. Variation in species present and stoichiometry suggests substantial oceanic microbial diversity.

Marine Metagenomics

With oceans covering 70% of our planet and one milliliter of seawater containing 10,000–1,000,000 microbes (1), there is clear impetus for researchers to identify and access this plethora of genomic information, which could offer a better understanding of these microbes' role in regulating and responding to global climate changes and other critical ecosystem processes.

But as much as researchers have their eye on the yet-untapped genetic sequences of marine microbial species, these millions of unseen ocean inhabitants aren't exactly suited to conventional DNA sequencing, which requires a culture of identical cells. Fortunately for those interested in deciphering the ocean's metagenome—that is, the collection of microbial genes in this mixed environmental sample—recent advances in sequencing technology and computational power are starting to break below the surface on the importance of ocean microbes.

Trends in Expression

"We need a whole earth catalog of genes and genomes to help us describe processes driven

ABOUT

MG-RAST (THE METAGENOMICS RAST) SERVER IS AN AUTOMATED ANALYSIS PLATFORM FOR METAGENOMES PROVIDING QUANTITATIVE INSIGHTS INTO MICROBIAL POPULATIONS BASED ON SEQUENCE DATA.

# OF METAGENOMES	
# BASE PAIRS	31,574
# OF SEQUENCES	4.08 TBP
# OF PUBLIC METAGENOMES	35.78 BILLION
	4,336

THE SERVER PROVIDES WEB BASED UPLOAD, QUALITY CONTROL, AUTOMATED ANNOTATION AND ANALYSIS FOR SAMPLES UP TO 10GBP. COMPARISON BETWEEN LARGE NUMBERS OF SAMPLES IS ENABLED VIA PRE-COMPUTED ABUNDANCE PROFILES. MG-RAST WAS LAUNCHED IN 2007 AND HAS OVER 5000 REGISTERED USERS AND 31,574 DATA SETS. THE CURRENT SERVER VERSION IS 3.1.

New Insights into the Diversity of Marine Picoeukaryotes

Fabrice Not^{1,2*}, Javier del Campo¹, Vanessa Balagué¹, Colomaban de Vargas², Ramon Massana¹

1 Institut de Ciències del Mar, CSIC, Barcelona, Spain, **2** Station Biologique de Roscoff, UMR7144, Evolution du Plancton et Paléocéans (EPPO), Centre National de la Recherche Scientifique (CNRS) et Université Pierre et Marie Curie (UPMC), Place George Teissier, Roscoff, France

Abstract

Over the last decade, culture-independent surveys of marine picoeukaryotic diversity based on 18S ribosomal DNA clone libraries have unveiled numerous sequences of novel high-rank taxa. This newfound diversity has significantly altered our understanding of marine microbial food webs and the evolution of eukaryotes. However, the current picture of marine eukaryotic biodiversity may be significantly skewed by PCR amplification biases, occurrence of rDNA genes in multiple copies within a single cell, and the capacity of DNA to persist as extracellular material. In this study we performed an analysis of the metagenomic dataset from the *Global Ocean Survey* (GOS) expedition, seeking eukaryotic ribosomal signatures. This PCR-free approach revealed similar phylogenetic patterns to clone library surveys, suggesting that PCR steps do not impose major biases in the exploration of environmental DNA. The different cell size fractions within the GOS dataset, however, displayed a distinct picture. High protistan diversity in the <math><0.8\ \mu\text{m}</math> size fraction, in particular sequences from radiolarians and ciliates (and their absence in the 0.8–3 μm fraction), suggest that most of the DNA in this fraction comes from extracellular material from larger cells. In addition, we compared the phylogenetic patterns from rDNA and reverse transcribed rRNA 18S clone libraries from the same sample harvested in the Mediterranean Sea. The libraries revealed major differences, with taxa such as pelagophytes or picobiliphytes only detected in the 18S rRNA library. MAST (Marine Stramenopiles) appeared as potentially prominent grazers and we observed a significant decrease in the contribution of alveolate and radiolarian sequences, which overwhelmingly dominated rDNA libraries. The rRNA approach appears to be less affected by taxon-specific rDNA copy number and likely better depicts the biogeochemical significance of marine protists.
