

Effect of temperature on egg development time and hatching success of three congeneric Acartiid species (Copepoda: Calanoida) from the Straits of Malacca

4th International Zooplankton Production Symposium
May 28 – June 1, 2007, Hiroshima, Japan

Yoshida T, Liong CF, Toda T
& Othman BHR
Universiti Kebangsaan Malaysia

Overview

- Egg development times (EDT) of three congeneric *Acartia* species
- Importance of *Acartia* spp. in the Straits of Malacca
- Biological significance of temperature on egg development

Introduction

- Development rates important in predicting secondary production.
- Observations in tropical regions limited.
- *Acartia erythraea*, *A. pacifica* and *A. spinicauda* are one of the dominant copepods in the Straits of Malacca (Rezai et al. 2004, Yoshida et al. 2006).

Introduction

A. clausi (L. Striven, Scotland; McLaren 1978)

A. clausi (Nova Scotia; McLaren 1969)

A. hudsonica (Onagawa Bay, Japan; Uye 1980)

Objectives

To examine temperature effects on:

- Egg development time (EDT)
- Hatching success

of the three congeneric Acartiid copepods from the tropical waters of the Straits of Malacca

Materials and Methods

Sampling site

Straits of Malacca (nearshore)
Average depth = 6 m
Plankton net: 300 μm

Live samples brought back to
Marine Science Station University
Putra Malaysia within 30 min.

Materials and Methods

10–50 μm prey size
natural seston

Incubation: 26 $^{\circ}\text{C}$

Acrylic incubation chamber

50 ml beaker

140 μm mesh bottom

Acartia (♀)

eggs

Materials and Methods

Eggs:

- Transferred to multi-well dish
- 5 ml filtered seawater (0.22 μm Millipore)
- Fresh eggs used (spawned within 2 hr)

EDT experiments:

- Incubation temperatures 10, 14, 18, 22, 27, 31 °C
- Hatching of eggs checked periodically
- EDT defined by Belehrádek's function
- Hatching success calculated

Egg development time

Species	Equation	Correlation coefficient
<i>A. erythraea</i>	$D = 294(T-4.47)^{-2.05}$	$r = 0.980$
<i>A. pacifica</i>	$D = 545(T-2.16)^{-2.05}$	$r = 0.983$
<i>A. spinicauda</i>	$D = 352(T-4.30)^{-2.05}$	$r = 0.996$

Belehrádek's temperature function

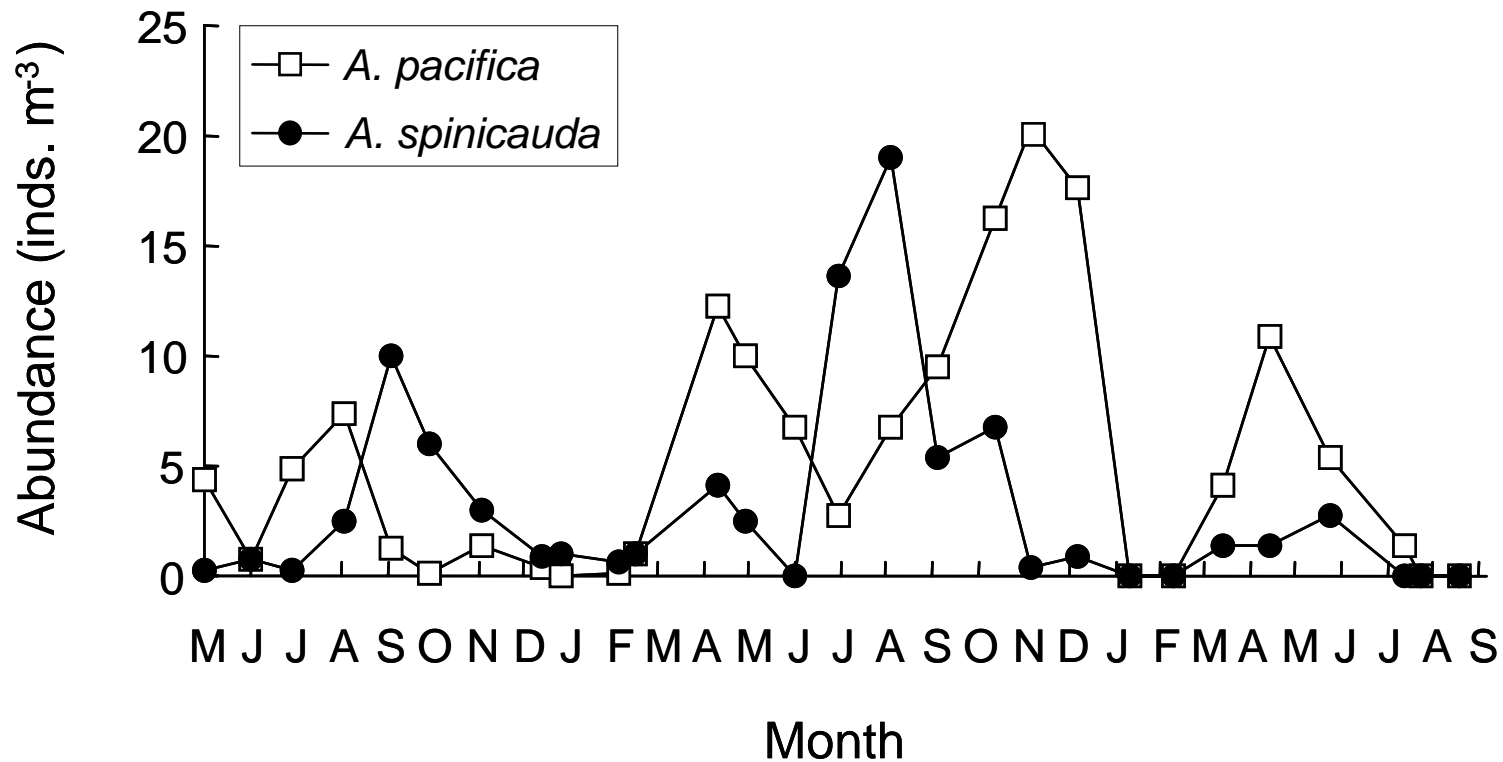

$$D = a(T - \alpha)^b$$

D : development time (days)

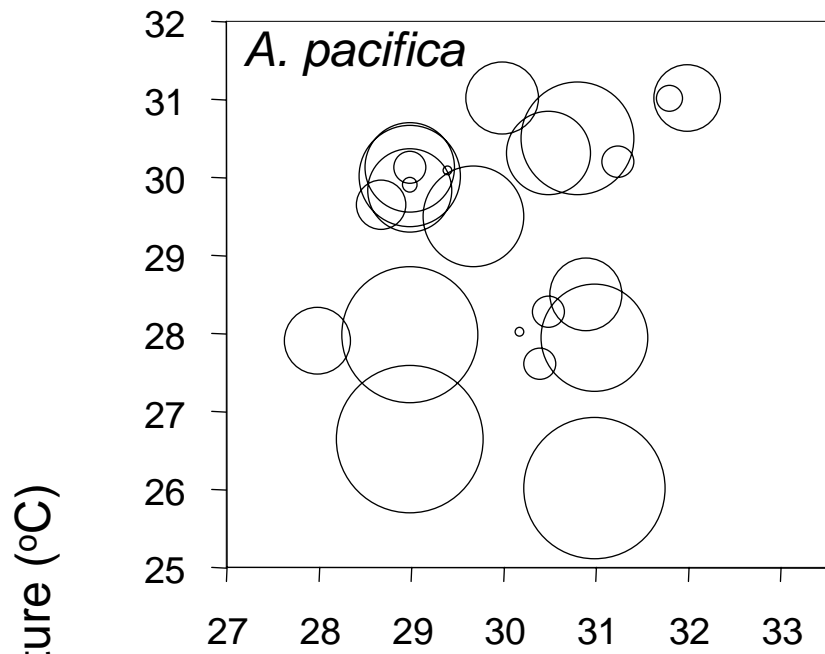

T : temperature (°C)

α : 'biological zero'

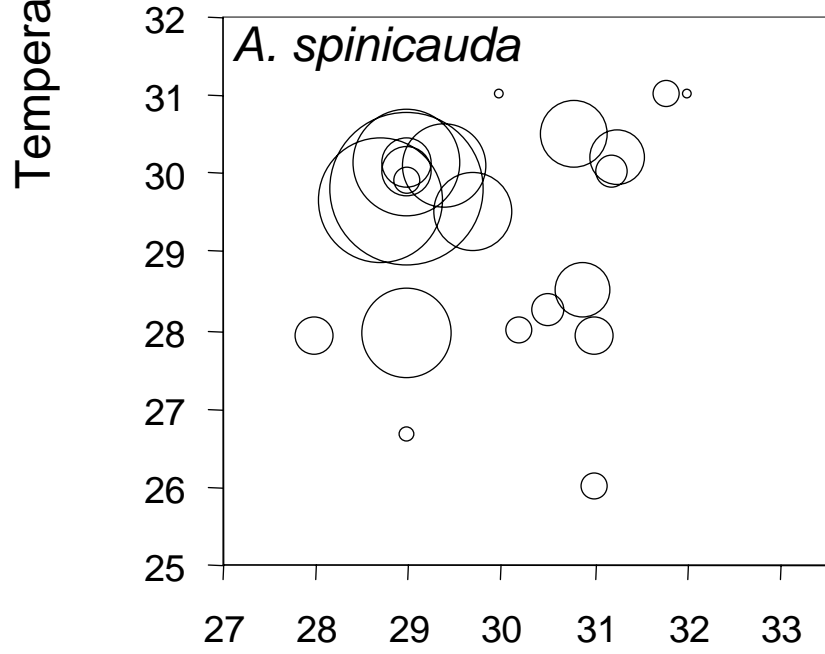

Seasonal variation of *Acartia pacifica* and *A. spinicauda* abundance at a fixed station in the Straits of Malacca (Yoshida et al. 2006)

Low temperature
High salinity

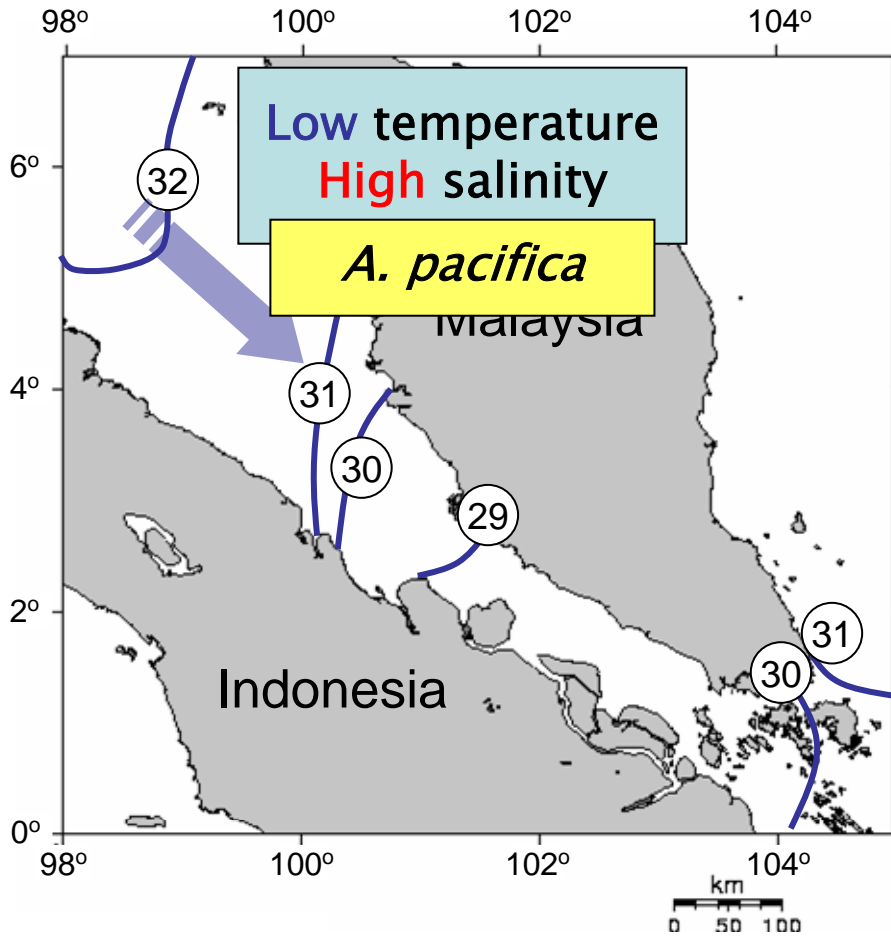

Scale (inds. m⁻³)

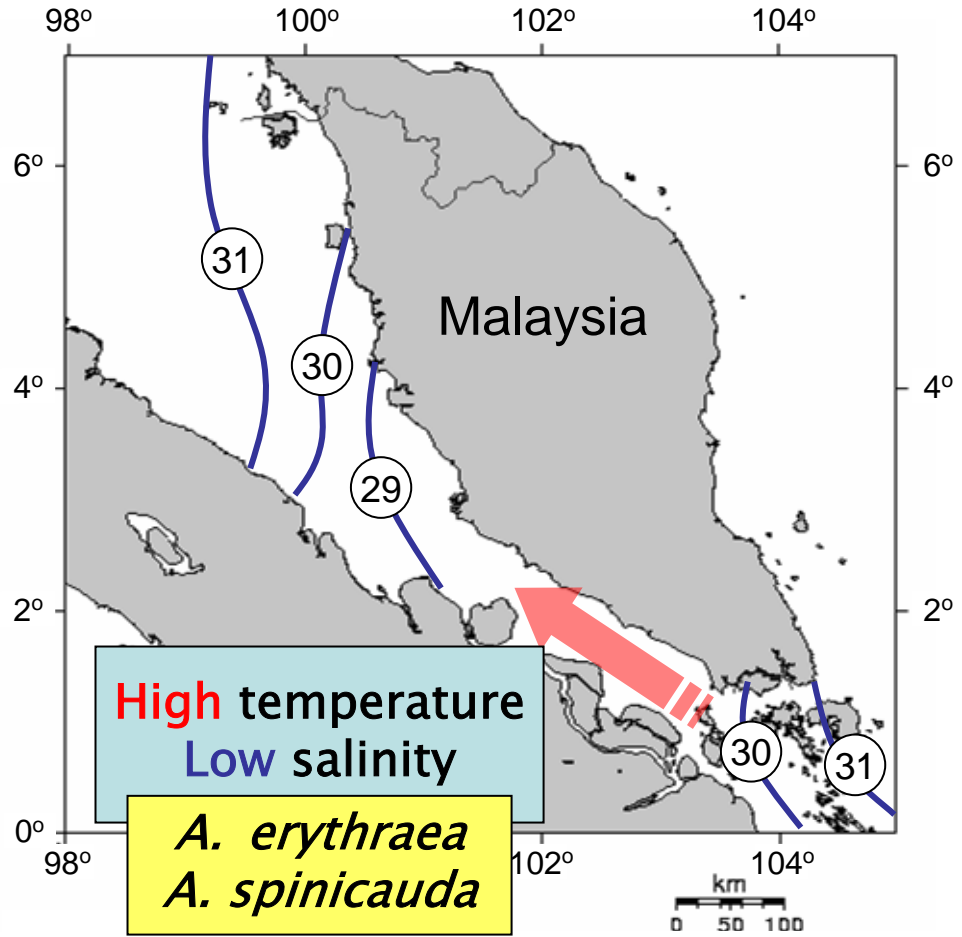

High temperature
Low salinity

Temperature-salinity distribtuion of *A. pacifica* and *A. spinicauda* (Yoshida et al. 2006)

SW monsoon

NE monsoon

Average surface salinity in the Straits of Malacca

Subpolar Temperate Tropical

A. clausi
A. longiremis
A. clausi

A. hudsonica
A. steueri
A. grani
A. tonsa

A. pacifica
A. spinicauda
A. erythraea

● Variation in EDT:
Different geographic
temperature acclimations

Hatching success

■ <i>A. erythrae</i>	61 %
□ <i>A. pacifica</i>	78 %
▨ <i>A. spinicauda</i>	87 %

Mean hatching success (14–31 °C)

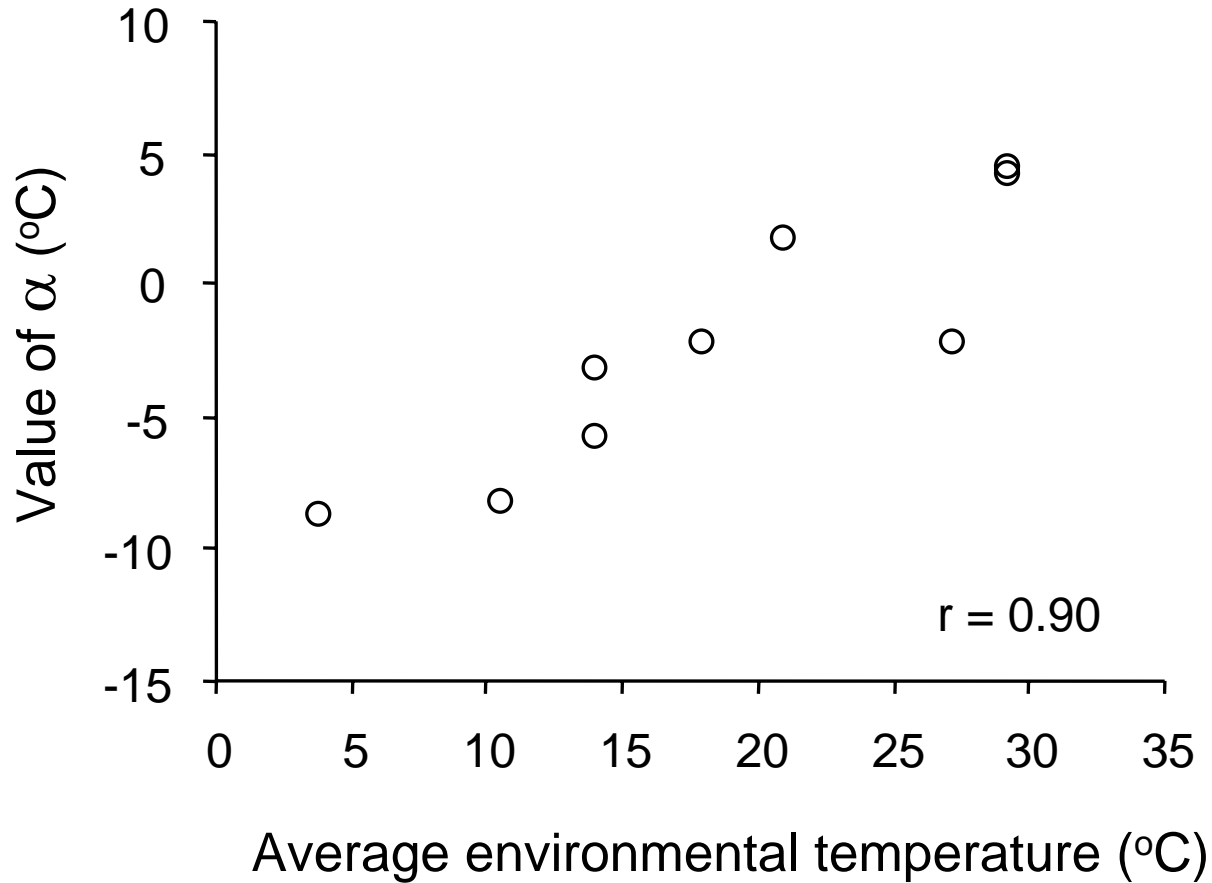

Other studies:

A. clausi
>80 % at 18–25 °C
0 % at 5 °C
(Uye & Fleminger 1976)

A. steueri
>80 % at 10–25 °C
(Uye 1980)

A. tonsa
60–90 % at 12.4–22.4 °C
0 % at <10 °C
(Holste & Peck 2006)

'Biological zero' & environmental temperature

Conclusions

- EDTs of the three *Acartia* species are closely described as functions of temperature.
- Variation in 'bio-zero' between species reflect differences in geographic temperature adaptation.
- High hatching success over wide temperature range characteristic of coastal species.
- Variance in development rates present even within tropical regions.
